createuser [connection-option...] [option...] [username]
```

## Description

createuser creates a new user (or more precisely, a role). Only superusers and users with `CREATEROLE` privilege can create new users, so createuser must be invoked by someone who can connect as a superuser or a user with `CREATEROLE` privilege.

If you wish to create a new superuser, you must connect as a superuser, not merely with `CREATEROLE` privilege. Being a superuser implies the ability to bypass all access permission checks within the database, so superuserdom should not be granted lightly.

createuser is a wrapper around the SQL command `CREATE ROLE`. There is no effective difference between creating users via this utility and via other methods for accessing the server.

## Options

createuser accepts the following command-line arguments:

*username*

Specifies the name of the user to be created. This name must be different from all existing roles in this installation.

`-c` *number*

`--connection-limit=number`

Set a maximum number of connections for the new user. The default is to set no limit.

`-d`

`--createdb`

The new user will be allowed to create databases.

`-D`

`--no-createdb`

The new user will not be allowed to create databases. This is the default.

`-e`

`--echo`

Echo the commands that createuser generates and sends to the server.

`-E`

`--encrypted`

This option is obsolete but still accepted for backward compatibility.

`-g` *role*

`--role=role`

Indicates role to which this role will be added immediately as a new member. Multiple roles to which this role will be added as a member can be specified by writing multiple `-g` switches.

`-i`  
`--inherit`  
The new role will automatically inherit privileges of roles it is a member of. This is the default.

`-I`  
`--no-inherit`  
The new role will not automatically inherit privileges of roles it is a member of.

`--interactive`  
Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options `-d/-D`, `-r/-R`, `-s/-S` is not specified on the command line. (This was the default behavior up to PostgreSQL 9.1.)

`-l`  
`--login`  
The new user will be allowed to log in (that is, the user name can be used as the initial session user identifier). This is the default.

`-L`  
`--no-login`  
The new user will not be allowed to log in. (A role without login privilege is still useful as a means of managing database permissions.)

`-P`  
`--pwprompt`  
If given, `createuser` will issue a prompt for the password of the new user. This is not necessary if you do not plan on using password authentication.

`-r`  
`--createrole`  
The new user will be allowed to create new roles (that is, this user will have `CREATEROLE` privilege).

`-R`  
`--no-createrole`  
The new user will not be allowed to create new roles. This is the default.

`-s`  
`--superuser`  
The new user will be a superuser.

`-S`  
`--no-superuser`  
The new user will not be a superuser. This is the default.

`-V`  
`--version`  
Print the `createuser` version and exit.

`--replication`  
The new user will have the `REPLICATION` privilege, which is described more fully in the documentation for `CREATE ROLE`.

`--no-replication`  
The new user will not have the `REPLICATION` privilege, which is described more fully in the documentation for `CREATE ROLE`.

-?  
--help

Show help about createuser command line arguments, and exit.

createuser also accepts the following command-line arguments for connection parameters:

-h *host*  
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*  
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U *username*  
--username=*username*

User name to connect as (not the user name to create).

-w  
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W  
--password

Force createuser to prompt for a password (for connecting to the server, not for the password of the new user).

This option is never essential, since createuser will automatically prompt for a password if the server demands password authentication. However, createuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

## Environment

PGHOST  
PGPORT  
PGUSER

Default connection parameters

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Diagnostics

In case of difficulty, see CREATE ROLE and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To create a user `joe` on the default database server:

```
$ createuser joe
```

To create a user `joe` on the default database server with prompting for some additional attributes:

```
$ createuser --interactive joe
Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n
```

To create the same user `joe` using the server on host `eden`, port `5000`, with attributes explicitly specified, taking a look at the underlying command:

```
$ createuser -h eden -p 5000 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT LOGIN;
```

To create the user `joe` as a superuser, and assign a password immediately:

```
$ createuser -P -s -e joe
Enter password for new role: xyzyy
Enter it again: xyzyy
CREATE ROLE joe PASSWORD 'md5b5f5ba1a423792b526f799ae4eb3d59e' SUPERUSER CREATEDB
CREATEROLE INHERIT LOGIN;
```

In the above example, the new password isn't actually echoed when typed, but we show what was typed for clarity. As you see, the password is encrypted before it is sent to the client.

# dropdb

dropdb — remove a database

## Synopsis

```
dropdb [connection-option...] [option...] dbname
```

## Description

dropdb destroys an existing database. The user who executes this command must be a database superuser or the owner of the database.

dropdb is a wrapper around the SQL command DROP DATABASE. There is no effective difference between dropping databases via this utility and via other methods for accessing the server.

## Options

dropdb accepts the following command-line arguments:

*dbname*

Specifies the name of the database to be removed.

-e

--echo

Echo the commands that dropdb generates and sends to the server.

-i

--interactive

Issues a verification prompt before doing anything destructive.

-V

--version

Print the dropdb version and exit.

--if-exists

Do not throw an error if the database does not exist. A notice is issued in this case.

-?

--help

Show help about dropdb command line arguments, and exit.

dropdb also accepts the following command-line arguments for connection parameters:

-h *host*

--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*

--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force dropdb to prompt for a password before connecting to a database.

This option is never essential, since dropdb will automatically prompt for a password if the server demands password authentication. However, dropdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to in order to drop the target database. If not specified, the `postgres` database will be used; if that does not exist (or is the database being dropped), `template1` will be used.

## Environment

PGHOST  
PGPORT  
PGUSER

Default connection parameters

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Diagnostics

In case of difficulty, see DROP DATABASE and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To destroy the database `demo` on the default database server:

```
$ dropdb demo
```

To destroy the database `demo` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropdb -p 5000 -h eden -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE demo;
```

# dropuser

dropuser — remove a user account

## Synopsis

```
dropuser [connection-option...] [option...] [username]
```

## Description

dropuser removes an existing user. Only superusers and users with the `CREATEROLE` privilege can remove users. (To remove a superuser, you must yourself be a superuser.)

dropuser is a wrapper around the SQL command `DROP ROLE`. There is no effective difference between dropping users via this utility and via other methods for accessing the server.

## Options

dropuser accepts the following command-line arguments:

*username*

Specifies the name of the user to be removed. You will be prompted for a name if none is specified on the command line and the `-i/--interactive` option is used.

`-e`  
`--echo`

Echo the commands that dropuser generates and sends to the server.

`-i`  
`--interactive`

Prompt for confirmation before actually removing the user, and prompt for the user name if none is specified on the command line.

`-V`  
`--version`

Print the dropuser version and exit.

`--if-exists`

Do not throw an error if the user does not exist. A notice is issued in this case.

`-?`  
`--help`

Show help about dropuser command line arguments, and exit.

dropuser also accepts the following command-line arguments for connection parameters:

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as (not the user name to drop).

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force dropuser to prompt for a password before connecting to a database.

This option is never essential, since dropuser will automatically prompt for a password if the server demands password authentication. However, dropuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Diagnostics

In case of difficulty, see `DROP ROLE` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To remove user `joe` from the default database server:

```
$ dropuser joe
```

To remove user `joe` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropuser -p 5000 -h eden -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE joe;
```

## ecpg

ecpg — embedded SQL C preprocessor

### Synopsis

ecpg [*option...*] *file...*

### Description

ecpg is the embedded SQL preprocessor for C programs. It converts C programs with embedded SQL statements to normal C code by replacing the SQL invocations with special function calls. The output files can then be processed with any C compiler tool chain.

ecpg will convert each input file given on the command line to the corresponding C output file. Input files preferably have the extension `.pgc`. The extension will be replaced by `.c` to determine the output file name. The output file name can also be overridden using the `-o` option.

This reference page does not describe the embedded SQL language. See Chapter 36 for more information on that topic.

### Options

ecpg accepts the following command-line arguments:

- `-c`  
Automatically generate certain C code from SQL code. Currently, this works for `EXEC SQL TYPE`.
- `-C mode`  
Set a compatibility mode. *mode* can be `INFORMIX` or `INFORMIX_SE`.
- `-D symbol`  
Define a C preprocessor symbol.
- `-i`  
Parse system include files as well.
- `-I directory`  
Specify an additional include path, used to find files included via `EXEC SQL INCLUDE`. Defaults are `.` (current directory), `/usr/local/include`, the include directory which is defined at compile time (default: `/usr/local/pgsql/include`), and `/usr/include`, in that order.
- `-o filename`  
Specifies that `ecpg` should write all its output to the given *filename*.
- `-r option`  
Selects run-time behavior. *Option* can be one of the following:
  - `no_indicator`  
Do not use indicators but instead use special values to represent null values. Historically there have been databases using this approach.
  - `prepare`  
Prepare all statements before using them. Libecpg will keep a cache of prepared statements and reuse a statement if it gets executed again. If the cache runs full, libecpg will free the least used statement.

questionmarks

Allow question mark as placeholder for compatibility reasons. This used to be the default long ago.

-t

Turn on autocommit of transactions. In this mode, each SQL command is automatically committed unless it is inside an explicit transaction block. In the default mode, commands are committed only when `EXEC SQL COMMIT` is issued.

-v

Print additional information including the version and the "include" path.

--version

Print the ecpg version and exit.

-?

--help

Show help about ecpg command line arguments, and exit.

## Notes

When compiling the preprocessed C code files, the compiler needs to be able to find the ECPG header files in the include directory. Therefore, you might have to use the `-I` option when invoking the compiler (e.g., `-I/usr/local/pgsql/include`).

Programs using C code with embedded SQL have to be linked against the `libecpg` library, for example using the linker options `-L/usr/local/pgsql/lib -lecpg`.

The value of either of these directories that is appropriate for the installation can be found out using `pg_config`.

## Examples

If you have an embedded SQL C source file named `prog1.pgc`, you can create an executable program using the following sequence of commands:

```
ecpg prog1.pgc
cc -I/usr/local/pgsql/include -c prog1.c
cc -o prog1 prog1.o -L/usr/local/pgsql/lib -lecpg
```

---

# pg\_basebackup

pg\_basebackup — take a base backup of a cluster

## Synopsis

```
pg_basebackup [option...]
```

## Description

pg\_basebackup is used to take base backups of a running database cluster. These are taken without affecting other clients to the database, and can be used both for point-in-time recovery (see Section 26.3) and as the starting point for a log shipping or streaming replication standby servers (see Section 27.2).

pg\_basebackup makes a binary copy of the database cluster files, while making sure the system is put in and out of backup mode automatically. Backups are always taken of the entire database cluster; it is not possible to back up individual databases or database objects. For individual database backups, a tool such as pg\_dump must be used.

The backup is made over a regular connection, and uses the replication protocol. The connection must be made with a superuser or a user having `REPLICATION` permissions (see Section 22.2), and `pg_hba.conf` must explicitly permit the replication connection. The server must also be configured with `max_wal_senders` set high enough to leave at least one session available for the backup and one for WAL streaming (if used).

There can be multiple `pg_basebackups` running at the same time, but it is better from a performance point of view to take only one backup, and copy the result.

pg\_basebackup can make a base backup from not only the master but also the standby. To take a backup from the standby, set up the standby so that it can accept replication connections (that is, set `max_wal_senders` and `hot_standby`, and configure host-based authentication). You will also need to enable `full_page_writes` on the master.

Note that there are some limitations in an online backup from the standby:

- The backup history file is not created in the database cluster backed up.
- If you are using `-X none`, there is no guarantee that all WAL files required for the backup are archived at the end of backup.
- If the standby is promoted to the master during online backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes, which requires you to enable `full_page_writes` on the master and not to use a tool like `pg_compresslog` as `archive_command` to remove full-page writes from WAL files.

## Options

The following command-line options control the location and format of the output.

```
-D directory  
--pgdata=directory
```

Directory to write the output to. `pg_basebackup` will create the directory and any parent directories if necessary. The directory may already exist, but it is an error if the directory already exists and is not empty.

When the backup is in tar mode, and the directory is specified as `-` (dash), the tar file will be written to `stdout`.

This option is required.

`-F format`  
`--format=format`

Selects the format for the output. *format* can be one of the following:

`p`  
`plain`

Write the output as plain files, with the same layout as the current data directory and tablespaces. When the cluster has no additional tablespaces, the whole database will be placed in the target directory. If the cluster contains additional tablespaces, the main data directory will be placed in the target directory, but all other tablespaces will be placed in the same absolute path as they have on the server.

This is the default format.

`t`  
`tar`

Write the output as tar files in the target directory. The main data directory will be written to a file named `base.tar`, and all other tablespaces will be named after the tablespace OID.

If the value `-` (dash) is specified as target directory, the tar contents will be written to standard output, suitable for piping to for example `gzip`. This is only possible if the cluster has no additional tablespaces and WAL streaming is not used.

`-r rate`  
`--max-rate=rate`

The maximum transfer rate of data transferred from the server. Values are in kilobytes per second. Use a suffix of `M` to indicate megabytes per second. A suffix of `k` is also accepted, and has no effect. Valid values are between 32 kilobytes per second and 1024 megabytes per second.

The purpose is to limit the impact of `pg_basebackup` on the running server.

This option always affects transfer of the data directory. Transfer of WAL files is only affected if the collection method is `fetch`.

`-R`  
`--write-recovery-conf`

Write a minimal `recovery.conf` in the output directory (or into the base archive file when using tar format) to ease setting up a standby server. The `recovery.conf` file will record the connection settings and, if specified, the replication slot that `pg_basebackup` is using, so that the streaming replication will use the same settings later on.

`-S slotname`  
`--slot=slotname`

This option can only be used together with `-X stream`. It causes the WAL streaming to use the specified replication slot. If the base backup is intended to be used as a streaming replication standby using replication slots, it should then use the same replication slot name in `recovery.conf`. That way, it is ensured that the server does not remove any necessary WAL data in the time between the end of the base backup and the start of streaming replication.

If this option is not specified and the server supports temporary replication slots (version 10 and later), then a temporary replication slot is automatically used for WAL streaming.

`--no-slot`

This option prevents the creation of a temporary replication slot during the backup even if it's supported by the server.

Temporary replication slots are created by default if no slot name is given with the option `-s` when using log streaming.

The main purpose of this option is to allow taking a base backup when the server is out of free replication slots. Using replication slots is almost always preferred, because it prevents needed WAL from being removed by the server during the backup.

```
-T olddir=newdir  
--tablespace-mapping=olddir=newdir
```

Relocate the tablespace in directory *olddir* to *newdir* during the backup. To be effective, *olddir* must exactly match the path specification of the tablespace as it is currently defined. (But it is not an error if there is no tablespace in *olddir* contained in the backup.) Both *olddir* and *newdir* must be absolute paths. If a path happens to contain a `=` sign, escape it with a backslash. This option can be specified multiple times for multiple tablespaces. See examples below.

If a tablespace is relocated in this way, the symbolic links inside the main data directory are updated to point to the new location. So the new data directory is ready to be used for a new server instance with all tablespaces in the updated locations.

```
--waldir=waldir
```

Specifies the location for the write-ahead log directory. *waldir* must be an absolute path. The write-ahead log directory can only be specified when the backup is in plain mode.

```
-X method  
--wal-method=method
```

Includes the required write-ahead log files (WAL files) in the backup. This will include all write-ahead logs generated during the backup. Unless the method `none` is specified, it is possible to start a postmaster directly in the extracted directory without the need to consult the log archive, thus making this a completely standalone backup.

The following methods for collecting the write-ahead logs are supported:

```
n  
none
```

Don't include write-ahead log in the backup.

```
f  
fetch
```

The write-ahead log files are collected at the end of the backup. Therefore, it is necessary for the `wal_keep_segments` parameter to be set high enough that the log is not removed before the end of the backup. If the log has been rotated when it's time to transfer it, the backup will fail and be unusable.

The write-ahead log files will be written to the `base.tar` file.

```
s  
stream
```

Stream the write-ahead log while the backup is created. This will open a second connection to the server and start streaming the write-ahead log in parallel while running the backup. Therefore, it will use up two connections configured by the `max_wal_senders` parameter. As long as the client can keep up with write-ahead log received, using this mode requires no extra write-ahead logs to be saved on the master.

The write-ahead log files are written to a separate file named `pg_wal.tar` (if the server is a version earlier than 10, the file will be named `pg_xlog.tar`).

This value is the default.

`-z`  
`--gzip`  
Enables gzip compression of tar file output, with the default compression level. Compression is only available when using the tar format, and the suffix `.gz` will automatically be added to all tar filenames.

`-Z level`  
`--compress=level`  
Enables gzip compression of tar file output, and specifies the compression level (0 through 9, 0 being no compression and 9 being best compression). Compression is only available when using the tar format, and the suffix `.gz` will automatically be added to all tar filenames.

The following command-line options control the generation of the backup and the running of the program.

`-c fast/spread`  
`--checkpoint=fast/spread`  
Sets checkpoint mode to fast (immediate) or spread (default) (see Section 26.3.3).

`-l label`  
`--label=label`  
Sets the label for the backup. If none is specified, a default value of “`pg_basebackup base backup`” will be used.

`-n`  
`--no-clean`  
By default, when `pg_basebackup` aborts with an error, it removes any directories it might have created before discovering that it cannot finish the job (for example, data directory and write-ahead log directory). This option inhibits tidying-up and is thus useful for debugging.

Note that tablespace directories are not cleaned up either way.

`-P`  
`--progress`  
Enables progress reporting. Turning this on will deliver an approximate progress report during the backup. Since the database may change during the backup, this is only an approximation and may not end at exactly 100%. In particular, when WAL log is included in the backup, the total amount of data cannot be estimated in advance, and in this case the estimated target size will increase once it passes the total estimate without WAL.

When this is enabled, the backup will start by enumerating the size of the entire database, and then go back and send the actual contents. This may make the backup take slightly longer, and in particular it will take longer before the first data is sent.

`-N`  
`--no-sync`  
By default, `pg_basebackup` will wait for all files to be written safely to disk. This option causes `pg_basebackup` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the base backup corrupt. Generally, this option is useful for testing but should not be used when creating a production installation.

`-v`  
`--verbose`  
Enables verbose mode. Will output some extra steps during startup and shutdown, as well as show the exact file name that is currently being processed if progress reporting is also enabled.

The following command-line options control the database connection parameters.

`-d connstr`  
`--dbname=connstr`

Specifies parameters used to connect to the server, as a connection string. See Section 34.1.1 for more information.

The option is called `--dbname` for consistency with other client applications, but because `pg_basebackup` doesn't connect to any particular database in the cluster, database name in the connection string will be ignored.

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-s interval`  
`--status-interval=interval`

Specifies the number of seconds between status packets sent back to the server. This allows for easier monitoring of the progress from server. A value of zero disables the periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout disconnect. The default value is 10 seconds.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_basebackup` to prompt for a password before connecting to a database.

This option is never essential, since `pg_basebackup` will automatically prompt for a password if the server demands password authentication. However, `pg_basebackup` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Other options are also available:

`-V`  
`--version`

Print the `pg_basebackup` version and exit.

`-?`  
`--help`

Show help about `pg_basebackup` command line arguments, and exit.

## Environment

This utility, like most other utilities, uses the environment variables supported by libpq (see Section 34.14).

## Notes

At the beginning of the backup, a checkpoint needs to be written on the server the backup is taken from. Especially if the option `--checkpoint=fast` is not used, this can take some time during which `pg_basebackup` will appear to be idle.

The backup will include all files in the data directory and tablespaces, including the configuration files and any additional files placed in the directory by third parties, except certain temporary files managed by `.tmpcheck`. But only regular files and directories are copied, except that symbolic links used for tablespaces are preserved. Symbolic links pointing to certain directories known to be copied as empty directories. Other symbolic links and special device files are skipped. See Section 53.4 for the precise details.

Tablespaces will in plain format by default be backed up to the same path they have on the server, unless the option `--tablespace-mapping` is used. Without this option, running a plain format base backup on the same host as the server will not work if tablespaces are in use, because the backup would have to be written to the same directory locations as the original tablespaces.

When tar format mode is used, it is the user's responsibility to unpack each tar file before starting the server. If there are additional tablespaces, the tar files for them need to be unpacked in the correct locations. In this case the symbolic links for those tablespaces will be created by the server according to the contents of the `tablespace_map` file that is included in the `base.tar` file.

`pg_basebackup` works with servers of the same or an older major version, down to 9.1. However, WAL streaming mode (`-X stream`) only works with server version 9.3 and later, and tar format mode (`--format=tar`) of the current version only works with server version 9.5 or later.

## Examples

To create a base backup of the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/data`:

```
$ pg_basebackup -h mydbserver -D /usr/local/pgsql/data
```

To create a backup of the local server with one compressed tar file for each tablespace, and store it in the directory `backup`, showing a progress report while running:

```
$ pg_basebackup -D backup -Ft -z -P
```

To create a backup of a single-tablespace local database and compress this with `bzip2`:

```
$ pg_basebackup -D - -Ft -X fetch | bzip2 > backup.tar.bz2
```

(This command will fail if there are multiple tablespaces in the database.)

To create a backup of a local database where the tablespace in `/opt/ts` is relocated to `./backup/ts`:

```
$ pg_basebackup -D backup/data -T /opt/ts=$(pwd)/backup/ts
```

# pgbench

pgbench — run a benchmark test on

## Synopsis

```
pgbench -i [option...] [dbname]
```

```
pgbench [option...] [dbname]
```

## Description

pgbench is a simple program for running benchmark tests on . It runs the same sequence of SQL commands over and over, possibly in multiple concurrent database sessions, and then calculates the average transaction rate (transactions per second). By default, pgbench tests a scenario that is loosely based on TPC-B, involving five `SELECT`, `UPDATE`, and `INSERT` commands per transaction. However, it is easy to test other cases by writing your own transaction script files.

Typical output from pgbench looks like:

```
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 10
query mode: simple
number of clients: 10
number of threads: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
tps = 85.184871 (including connections establishing)
tps = 85.296346 (excluding connections establishing)
```

The first six lines report some of the most important parameter settings. The next line reports the number of transactions completed and intended (the latter being just the product of number of clients and number of transactions per client); these will be equal unless the run failed before completion. (In `-T` mode, only the actual number of transactions is printed.) The last two lines report the number of transactions per second, figured with and without counting the time to start database sessions.

The default TPC-B-like transaction test requires specific tables to be set up beforehand. pgbench should be invoked with the `-i` (initialize) option to create and populate these tables. (When you are testing a custom script, you don't need this step, but will instead need to do whatever setup your test needs.) Initialization looks like:

```
pgbench -i [ other-options ] dbname
```

where *dbname* is the name of the already-created database to test in. (You may also need `-h`, `-p`, and/or `-U` options to specify how to connect to the database server.)

### Caution

pgbench `-i` creates four tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`, destroying any existing tables of these names. Be very careful to use another database if you have tables having these names!

At the default “scale factor” of 1, the tables initially contain this many rows:

table	# of rows
pgbench_branches	1
pgbench_tellers	10

```
pgbench_accounts      100000
pgbench_history        0
```

You can (and, for most purposes, probably should) increase the number of rows by using the `-s` (scale factor) option. The `-F` (fillfactor) option might also be used at this point.

Once you have done the necessary setup, you can run your benchmark with a command that doesn't include `-i`, that is

```
pgbench [ options ] dbname
```

In nearly all cases, you'll need some options to make a useful test. The most important options are `-c` (number of clients), `-t` (number of transactions), `-T` (time limit), and `-f` (specify a custom script file). See below for a full list.

## Options

The following is divided into three subsections: Different options are used during database initialization and while running benchmarks, some options are useful in both cases.

### Initialization Options

pgbench accepts the following command-line initialization arguments:

```
-i
--initialize
```

Required to invoke initialization mode.

```
-F fillfactor
--fillfactor=fillfactor
```

Create the `pgbench_accounts`, `pgbench_tellers` and `pgbench_branches` tables with the given fillfactor. Default is 100.

```
-n
--no-vacuum
```

Perform no vacuuming after initialization.

```
-q
--quiet
```

Switch logging to quiet mode, producing only one progress message per 5 seconds. The default logging prints one message each 100000 rows, which often outputs many lines per second (especially on good hardware).

```
-s scale_factor
--scale=scale_factor
```

Multiply the number of rows generated by the scale factor. For example, `-s 100` will create 10,000,000 rows in the `pgbench_accounts` table. Default is 1. When the scale is 20,000 or larger, the columns used to hold account identifiers (`aid` columns) will switch to using larger integers (`bigint`), in order to be big enough to hold the range of account identifiers.

```
--foreign-keys
```

Create foreign key constraints between the standard tables.

```
--index-tablespace=index_tablespace
```

Create indexes in the specified tablespace, rather than the default tablespace.

```
--tablespace=tablespace
```

Create tables in the specified tablespace, rather than the default tablespace.

`--unlogged-tables`

Create all tables as unlogged tables, rather than permanent tables.

## Benchmarking Options

pgbench accepts the following command-line benchmarking arguments:

`-b scriptname[@weight]`

`--builtin=scriptname[@weight]`

Add the specified built-in script to the list of executed scripts. An optional integer weight after @ allows to adjust the probability of drawing the script. If not specified, it is set to 1. Available built-in scripts are: `tpcb-like`, `simple-update` and `select-only`. Unambiguous prefixes of built-in names are accepted. With special name `list`, show the list of built-in scripts and exit immediately.

`-c clients`

`--client=clients`

Number of clients simulated, that is, number of concurrent database sessions. Default is 1.

`-C`

`--connect`

Establish a new connection for each transaction, rather than doing it just once per client session. This is useful to measure the connection overhead.

`-d`

`--debug`

Print debugging output.

`-D varname=value`

`--define=varname=value`

Define a variable for use by a custom script (see below). Multiple `-D` options are allowed.

`-f filename[@weight]`

`--file=filename[@weight]`

Add a transaction script read from `filename` to the list of executed scripts. An optional integer weight after @ allows to adjust the probability of drawing the test. See below for details.

`-j threads`

`--jobs=threads`

Number of worker threads within pgbench. Using more than one thread can be helpful on multi-CPU machines. Clients are distributed as evenly as possible among available threads. Default is 1.

`-l`

`--log`

Write information about each transaction to a log file. See below for details.

`-L limit`

`--latency-limit=limit`

Transaction which last more than `limit` milliseconds are counted and reported separately, as *late*.

When throttling is used (`--rate=...`), transactions that lag behind schedule by more than `limit` ms, and thus have no hope of meeting the latency limit, are not sent to the server at all. They are counted and reported separately as *skipped*.

`-M querymode`

`--protocol=querymode`

Protocol to use for submitting queries to the server:

- `simple`: use simple query protocol.
- `extended`: use extended query protocol.
- `prepared`: use extended query protocol with prepared statements.

The default is simple query protocol. (See Chapter 53 for more information.)

`-n`  
`--no-vacuum`

Perform no vacuuming before running the test. This option is *necessary* if you are running a custom test scenario that does not include the standard tables `pgbench_accounts`, `pgbench_branches`, `pgbench_history`, and `pgbench_tellers`.

`-N`  
`--skip-some-updates`

Run built-in simple-update script. Shorthand for `-b simple-update`.

`-P sec`  
`--progress=sec`

Show progress report every `sec` seconds. The report includes the time since the beginning of the run, the tps since the last report, and the transaction latency average and standard deviation since the last report. Under throttling (`-R`), the latency is computed with respect to the transaction scheduled start time, not the actual transaction beginning time, thus it also includes the average schedule lag time.

`-r`  
`--report-latencies`

Report the average per-statement latency (execution time from the perspective of the client) of each command after the benchmark finishes. See below for details.

`-R rate`  
`--rate=rate`

Execute transactions targeting the specified rate instead of running as fast as possible (the default). The rate is given in transactions per second. If the targeted rate is above the maximum possible rate, the rate limit won't impact the results.

The rate is targeted by starting transactions along a Poisson-distributed schedule time line. The expected start time schedule moves forward based on when the client first started, not when the previous transaction ended. That approach means that when transactions go past their original scheduled end time, it is possible for later ones to catch up again.

When throttling is active, the transaction latency reported at the end of the run is calculated from the scheduled start times, so it includes the time each transaction had to wait for the previous transaction to finish. The wait time is called the schedule lag time, and its average and maximum are also reported separately. The transaction latency with respect to the actual transaction start time, i.e. the time spent executing the transaction in the database, can be computed by subtracting the schedule lag time from the reported latency.

If `--latency-limit` is used together with `--rate`, a transaction can lag behind so much that it is already over the latency limit when the previous transaction ends, because the latency is calculated from the scheduled start time. Such transactions are not sent to the server, but are skipped altogether and counted separately.

A high schedule lag time is an indication that the system cannot process transactions at the specified rate, with the chosen number of clients and threads. When the average transaction execution time is longer than the scheduled interval between each transaction, each successive transaction will fall further behind, and the schedule lag time will keep increasing the longer the test run is. When that happens, you will have to reduce the specified transaction rate.

`-s scale_factor`  
`--scale=scale_factor`

Report the specified scale factor in pgbench's output. With the built-in tests, this is not necessary; the correct scale factor will be detected by counting the number of rows in the `pgbench_branches` table. However, when testing only custom benchmarks (`-f` option), the scale factor will be reported as 1 unless this option is used.

`-S`  
`--select-only`

Run built-in select-only script. Shorthand for `-b select-only`.

`-t transactions`  
`--transactions=transactions`

Number of transactions each client runs. Default is 10.

`-T seconds`  
`--time=seconds`

Run the test for this many seconds, rather than a fixed number of transactions per client. `-t` and `-T` are mutually exclusive.

`-v`  
`--vacuum-all`

Vacuum all four standard tables before running the test. With neither `-n` nor `-v`, pgbench will vacuum the `pgbench_tellers` and `pgbench_branches` tables, and will truncate `pgbench_history`.

`--aggregate-interval=seconds`

Length of aggregation interval (in seconds). May be used only with `-l` option. With this option, the log contains per-interval summary data, as described below.

`--log-prefix=prefix`

Set the filename prefix for the log files created by `--log`. The default is `pgbench_log`.

`--progress-timestamp`

When showing progress (option `-P`), use a timestamp (Unix epoch) instead of the number of seconds since the beginning of the run. The unit is in seconds, with millisecond precision after the dot. This helps compare logs generated by various tools.

`--sampling-rate=rate`

Sampling rate, used when writing data into the log, to reduce the amount of log generated. If this option is given, only the specified fraction of transactions are logged. 1.0 means all transactions will be logged, 0.05 means only 5% of the transactions will be logged.

Remember to take the sampling rate into account when processing the log file. For example, when computing tps values, you need to multiply the numbers accordingly (e.g. with 0.01 sample rate, you'll only get 1/100 of the actual tps).

## Common Options

pgbench accepts the following command-line common arguments:

`-h hostname`  
`--host=hostname`

The database server's host name

`-p port`

`--port=port`

The database server's port number

`-U login`

`--username=login`

The user name to connect as

`-V`

`--version`

Print the pgbench version and exit.

`-?`

`--help`

Show help about pgbench command line arguments, and exit.

## Notes

### What is the “Transaction” Actually Performed in pgbench?

pgbench executes test scripts chosen randomly from a specified list. They include built-in scripts with `-b` and user-provided custom scripts with `-f`. Each script may be given a relative weight specified after a `@` so as to change its drawing probability. The default weight is 1. Scripts with a weight of 0 are ignored.

The default built-in transaction script (also invoked with `-b tpcb-like`) issues seven commands per transaction over randomly chosen `aid`, `tid`, `bid` and `balance`. The scenario is inspired by the TPC-B benchmark, but is not actually TPC-B, hence the name.

1. `BEGIN;`
2. `UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;`
3. `SELECT abalance FROM pgbench_accounts WHERE aid = :aid;`
4. `UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;`
5. `UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;`
6. `INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);`
7. `END;`

If you select the `simple-update` built-in (also `-N`), steps 4 and 5 aren't included in the transaction. This will avoid update contention on these tables, but it makes the test case even less like TPC-B.

If you select the `select-only` built-in (also `-S`), only the `SELECT` is issued.

### Custom Scripts

pgbench has support for running custom benchmark scenarios by replacing the default transaction script (described above) with a transaction script read from a file (`-f` option). In this case a “transaction” counts as one execution of a script file.

A script file contains one or more SQL commands terminated by semicolons. Empty lines and lines beginning with `--` are ignored. Script files can also contain “meta commands”, which are interpreted by pgbench itself, as described below.

#### Note

Before 9.6, SQL commands in script files were terminated by newlines, and so they could not be continued across lines. Now a semicolon is *required* to separate consecutive SQL

commands (though a SQL command does not need one if it is followed by a meta command). If you need to create a script file that works with both old and new versions of pgbench, be sure to write each SQL command on a single line ending with a semicolon.

There is a simple variable-substitution facility for script files. Variables can be set by the command-line `-D` option, explained above, or by the meta commands explained below. In addition to any variables preset by `-D` command-line options, there are a few variables that are preset automatically, listed in Table 240. A value specified for these variables using `-D` takes precedence over the automatic presets. Once set, a variable's value can be inserted into a SQL command by writing `:variablename`. When running more than one client session, each session has its own set of variables.

**Table 240. Automatic Variables**

Variable	Description
scale	current scale factor
client_id	unique number identifying the client session (starts from zero)

Script file meta commands begin with a backslash (`\`) and normally extend to the end of the line, although they can be continued to additional lines by writing backslash-return. Arguments to a meta command are separated by white space. These meta commands are supported:

```
\set varname expression
```

Sets variable *varname* to a value calculated from *expression*. The expression may contain integer constants such as 5432, double constants such as 3.14159, references to variables `:variablename`, unary operators (+, -) and binary operators (+, -, \*, /, %) with their usual precedence and associativity, function calls, and parentheses.

Examples:

```
\set ntellers 10 * :scale
\set aid (1021 * random(1, 100000 * :scale)) % \
(100000 * :scale) + 1
```

```
\sleep number [ us | ms | s ]
```

Causes script execution to sleep for the specified duration in microseconds (`us`), milliseconds (`ms`) or seconds (`s`). If the unit is omitted then seconds are the default. *number* can be either an integer constant or a `:variablename` reference to a variable having an integer value.

Example:

```
\sleep 10 ms
```

```
\setshell varname command [ argument ... ]
```

Sets variable *varname* to the result of the shell command *command* with the given *argument(s)*. The command must return an integer value through its standard output.

*command* and each *argument* can be either a text constant or a `:variablename` reference to a variable. If you want to use an *argument* starting with a colon, write an additional colon at the beginning of *argument*.

Example:

```
\setshell variable_to_be_assigned command
literal_argument :variable ::literal_starting_with_colon
```

```
\shell command [ argument ... ]
```

Same as `\setshell`, but the result of the command is discarded.

Example:

```
\shell command literal_argument :variable ::literal_starting_with_colon
```

## Built-In Functions

The functions listed in Table 241 are built into pgbench and may be used in expressions appearing in `\set`.

**Table 241. pgbench Functions**

Function	Return Type	Description	Example	Result
<code>abs( a )</code>	same as <i>a</i>	absolute value	<code>abs(-17)</code>	17
<code>debug( a )</code>	same as <i>a</i>	print <i>a</i> to stderr, and return <i>a</i>	<code>debug(5432.1)</code>	5432.1
<code>double( i )</code>	double	cast to double	<code>double(5432)</code>	5432.0
<code>greatest( a [, ... ] )</code>	double if any <i>a</i> is double, else integer	largest value among arguments	<code>greatest(5, 4, 3, 2)</code>	5
<code>int( x )</code>	integer	cast to int	<code>int(5.4 + 3.8)</code>	9
<code>least( a [, ... ] )</code>	double if any <i>a</i> is double, else integer	smallest value among arguments	<code>least(5, 4, 3, 2.1)</code>	2.1
<code>pi()</code>	double	value of the constant PI	<code>pi()</code>	3.14159265358979323846
<code>random( lb, ub )</code>	integer	uniformly-distributed random integer in [ <i>lb</i> , <i>ub</i> ]	<code>random(1, 10)</code>	an integer between 1 and 10
<code>random_exponential( lb, ub, parameter )</code>	integer	exponentially-distributed random integer in [ <i>lb</i> , <i>ub</i> ], see below	<code>random_exponential(1, 10, 3.0)</code>	an integer between 1 and 10
<code>random_gaussian( lb, ub, parameter )</code>	integer	Gaussian-distributed random integer in [ <i>lb</i> , <i>ub</i> ], see below	<code>random_gaussian(1, 10, 2.5)</code>	an integer between 1 and 10
<code>sqrt( x )</code>	double	square root	<code>sqrt(2.0)</code>	1.414213562

The `random` function generates values using a uniform distribution, that is all the values are drawn within the specified range with equal probability. The `random_exponential` and `random_gaussian` functions require an additional double parameter which determines the precise shape of the distribution.

- For an exponential distribution, *parameter* controls the distribution by truncating a quickly-decreasing exponential distribution at *parameter*, and then projecting onto integers between the bounds. To be precise, with

$$f(x) = \exp(-\text{parameter} * (x - \text{min}) / (\text{max} - \text{min} + 1)) / (1 - \exp(-\text{parameter}))$$

Then value *i* between *min* and *max* inclusive is drawn with probability:  $f(i) - f(i + 1)$ .

Intuitively, the larger the *parameter*, the more frequently values close to *min* are accessed, and the less frequently values close to *max* are accessed. The closer to 0 *parameter* is, the flatter (more uniform) the access distribution. A crude approximation of the distribution is that the most frequent 1% values in the range, close to *min*, are drawn *parameter*% of the time. The *parameter* value must be strictly positive.

- For a Gaussian distribution, the interval is mapped onto a standard normal distribution (the classical bell-shaped Gaussian curve) truncated at `-parameter` on the left and `+parameter` on the right.

Values in the middle of the interval are more likely to be drawn. To be precise, if  $\text{PHI}(x)$  is the cumulative distribution function of the standard normal distribution, with mean  $\mu$  defined as  $(\max + \min) / 2.0$ , with

$$f(x) = \frac{\text{PHI}(2.0 * \text{parameter} * (x - \mu) / (\max - \min + 1))}{(2.0 * \text{PHI}(\text{parameter}) - 1)}$$

then value  $i$  between  $\min$  and  $\max$  inclusive is drawn with probability:  $f(i + 0.5) - f(i - 0.5)$ . Intuitively, the larger the *parameter*, the more frequently values close to the middle of the interval are drawn, and the less frequently values close to the *min* and *max* bounds. About 67% of values are drawn from the middle  $1.0 / \text{parameter}$ , that is a relative  $0.5 / \text{parameter}$  around the mean, and 95% in the middle  $2.0 / \text{parameter}$ , that is a relative  $1.0 / \text{parameter}$  around the mean; for instance, if *parameter* is 4.0, 67% of values are drawn from the middle quarter ( $1.0 / 4.0$ ) of the interval (i.e. from  $3.0 / 8.0$  to  $5.0 / 8.0$ ) and 95% from the middle half ( $2.0 / 4.0$ ) of the interval (second and third quartiles). The minimum *parameter* is 2.0 for performance of the Box-Muller transform.

As an example, the full definition of the built-in TPC-B-like transaction is:

```
\set aid random(1, 100000 * :scale)
\set bid random(1, 1 * :scale)
\set tid random(1, 10 * :scale)
\set delta random(-5000, 5000)
BEGIN;
UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
END;
```

This script allows each iteration of the transaction to reference different, randomly-chosen rows. (This example also shows why it's important for each client session to have its own variables — otherwise they'd not be independently touching different rows.)

## Per-Transaction Logging

With the `-l` option (but without the `--aggregate-interval` option), `pgbench` writes information about each transaction to a log file. The log file will be named `prefix.nnn`, where `prefix` defaults to `pgbench_log`, and `nnn` is the PID of the `pgbench` process. The prefix can be changed by using the `--log-prefix` option. If the `-j` option is 2 or higher, so that there are multiple worker threads, each will have its own log file. The first worker will use the same name for its log file as in the standard single worker case. The additional log files for the other workers will be named `prefix.nnn.mmm`, where `mmm` is a sequential number for each worker starting with 1.

The format of the log is:

```
client_id transaction_no time script_no time_epoch time_us [ schedule_lag ]
```

where `client_id` indicates which client session ran the transaction, `transaction_no` counts how many transactions have been run by that session, `time` is the total elapsed transaction time in microseconds, `script_no` identifies which script file was used (useful when multiple scripts were specified with `-f` or `-b`), and `time_epoch/time_us` are a Unix-epoch time stamp and an offset in microseconds (suitable for creating an ISO 8601 time stamp with fractional seconds) showing when the transaction completed. The `schedule_lag` field is the difference between the transaction's scheduled start time, and the time it actually started, in microseconds. It is only present when the `--rate` option is used. When both `--rate` and `--latency-limit` are used, the `time` for a skipped transaction will be reported as `skipped`.

Here is a snippet of a log file generated in a single-client run:

```
0 199 2241 0 1175850568 995598
```

```
0 200 2465 0 1175850568 998079
0 201 2513 0 1175850569 608
0 202 2038 0 1175850569 2663
```

Another example with `--rate=100` and `--latency-limit=5` (note the additional `schedule_lag` column):

```
0 81 4621 0 1412881037 912698 3005
0 82 6173 0 1412881037 914578 4304
0 83 skipped 0 1412881037 914578 5217
0 83 skipped 0 1412881037 914578 5099
0 83 4722 0 1412881037 916203 3108
0 84 4142 0 1412881037 918023 2333
0 85 2465 0 1412881037 919759 740
```

In this example, transaction 82 was late, because its latency (6.173 ms) was over the 5 ms limit. The next two transactions were skipped, because they were already late before they were even started.

When running a long test on hardware that can handle a lot of transactions, the log files can become very large. The `--sampling-rate` option can be used to log only a random sample of transactions.

## Aggregated Logging

With the `--aggregate-interval` option, a different format is used for the log files:

```
interval_start num_transactions sum_latency sum_latency_2 min_latency max_latency
[ sum_lag sum_lag_2 min_lag max_lag [ skipped ] ]
```

where `interval_start` is the start of the interval (as a Unix epoch time stamp), `num_transactions` is the number of transactions within the interval, `sum_latency` is the sum of the transaction latencies within the interval, `sum_latency_2` is the sum of squares of the transaction latencies within the interval, `min_latency` is the minimum latency within the interval, and `max_latency` is the maximum latency within the interval. The next fields, `sum_lag`, `sum_lag_2`, `min_lag`, and `max_lag`, are only present if the `--rate` option is used. They provide statistics about the time each transaction had to wait for the previous one to finish, i.e. the difference between each transaction's scheduled start time and the time it actually started. The very last field, `skipped`, is only present if the `--latency-limit` option is used, too. It counts the number of transactions skipped because they would have started too late. Each transaction is counted in the interval when it was committed.

Here is some example output:

```
1345828501 5601 1542744 483552416 61 2573
1345828503 7884 1979812 565806736 60 1479
1345828505 7208 1979422 567277552 59 1391
1345828507 7685 1980268 569784714 60 1398
1345828509 7073 1979779 573489941 236 1411
```

Notice that while the plain (unaggregated) log file shows which script was used for each transaction, the aggregated log does not. Therefore if you need per-script data, you need to aggregate the data on your own.

## Per-Statement Latencies

With the `-r` option, `pgbench` collects the elapsed transaction time of each statement executed by every client. It then reports an average of those values, referred to as the latency for each statement, after the benchmark has finished.

For the default script, the output will look similar to this:

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
```

```
number of threads: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
latency average = 15.844 ms
latency stddev = 2.715 ms
tps = 618.764555 (including connections establishing)
tps = 622.977698 (excluding connections establishing)
script statistics:
- statement latencies in milliseconds:
    0.002  \set aid random(1, 100000 * :scale)
    0.005  \set bid random(1, 1 * :scale)
    0.002  \set tid random(1, 10 * :scale)
    0.001  \set delta random(-5000, 5000)
    0.326  BEGIN;
    0.603  UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid
= :aid;
    0.454  SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
    5.528  UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid
= :tid;
    7.335  UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid
= :bid;
    0.371  INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES
(:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
    1.212  END;
```

If multiple script files are specified, the averages are reported separately for each script file.

Note that collecting the additional timing information needed for per-statement latency computation adds some overhead. This will slow average execution speed and lower the computed TPS. The amount of slowdown varies significantly depending on platform and hardware. Comparing average TPS values with and without latency reporting enabled is a good way to measure if the timing overhead is significant.

## Good Practices

It is very easy to use `pgbench` to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, *never* believe any test that runs for only a few seconds. Use the `-t` or `-T` option to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It's a good idea to try the test run a few times, to find out if your numbers are reproducible or not.

For the default TPC-B-like test scenario, the initialization scale factor (`-s`) should be at least as large as the largest number of clients you intend to test (`-c`); else you'll mostly be measuring update contention. There are only `-s` rows in the `pgbench_branches` table, and every transaction wants to update one of them, so `-c` values in excess of `-s` will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it's been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If `autovacuum` is enabled it can result in unpredictable changes in measured performance.

A limitation of `pgbench` is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running `pgbench` on a different machine from the database server, although low network latency will be essential. It might even be useful to run several `pgbench` instances concurrently, on several client machines, against the same database server.

---

# pg\_config

pg\_config — retrieve information about the installed version of

## Synopsis

```
pg_config [option...]
```

## Description

The `pg_config` utility prints configuration parameters of the currently installed version of `PostgreSQL`. It is intended, for example, to be used by software packages that want to interface to `PostgreSQL` to facilitate finding the required header files and libraries.

## Options

To use `pg_config`, supply one or more of the following options:

`--bindir`

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

`--docdir`

Print the location of documentation files.

`--htmldir`

Print the location of HTML documentation files.

`--includedir`

Print the location of C header files of the client interfaces.

`--pkgincludedir`

Print the location of other C header files.

`--includedir-server`

Print the location of C header files for server programming.

`--libdir`

Print the location of object code libraries.

`--pkglibdir`

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files might also be installed in this directory.)

`--localedir`

Print the location of locale support files. (This will be an empty string if locale support was not configured when `PostgreSQL` was built.)

`--mandir`

Print the location of manual pages.

`--sharedir`

Print the location of architecture-independent support files.

`--sysconfdir`

Print the location of system-wide configuration files.

`--pgxs`

Print the location of extension makefiles.

`--configure`

Print the options that were given to the `configure` script when was configured for building. This can be used to reproduce the identical configuration, or to find out with what options a binary package was built. (Note however that binary packages often contain vendor-specific custom patches.) See also the examples below.

`--cc`

Print the value of the `CC` variable that was used for building . This shows the C compiler used.

`--cppflags`

Print the value of the `CPPFLAGS` variable that was used for building . This shows C compiler switches needed at preprocessing time (typically, `-I` switches).

`--cflags`

Print the value of the `CFLAGS` variable that was used for building . This shows C compiler switches.

`--cflags_sl`

Print the value of the `CFLAGS_SL` variable that was used for building . This shows extra C compiler switches used for building shared libraries.

`--ldflags`

Print the value of the `LDFLAGS` variable that was used for building . This shows linker switches.

`--ldflags_ex`

Print the value of the `LDFLAGS_EX` variable that was used for building . This shows linker switches used for building executables only.

`--ldflags_sl`

Print the value of the `LDFLAGS_SL` variable that was used for building . This shows linker switches used for building shared libraries only.

`--libs`

Print the value of the `LIBS` variable that was used for building . This normally contains `-l` switches for external libraries linked into .

`--version`

Print the version of .

`-?`

`--help`

Show help about `pg_config` command line arguments, and exit.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

## Notes

The options `--docdir`, `--pkgincludedir`, `--localedir`, `--mandir`, `--sharedir`, `--sysconfdir`, `--cc`, `--cppflags`, `--cflags`, `--cflags_sl`, `--ldflags`, `--ldflags_sl`, and `--libs` were added in PostgreSQL

8.1. The option `--htmldir` was added in PostgreSQL 8.4. The option `--ldflags_ex` was added in PostgreSQL 9.0.

## Example

To reproduce the build configuration of the current installation, run the following command:

```
eval `./configure `pg_config --configure`
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

---

# pg\_dump

`pg_dump` — extract a database into a script file or other archive file

## Synopsis

```
pg_dump [connection-option...] [option...] [dbname]
```

## Description

`pg_dump` is a utility for backing up a database. It makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

`pg_dump` only dumps a single database. To backup global objects that are common to all databases in a cluster, such as roles and tablespaces, use `pg_dumpall`.

Dumps can be output in script or archive file formats. Script dumps are plain-text files containing the SQL commands required to reconstruct the database to the state it was in at the time it was saved. To restore from such a script, feed it to `psql`. Script files can be used to reconstruct the database even on other machines and other architectures; with some modifications, even on other SQL database products.

The alternative archive file formats must be used with `pg_restore` to rebuild the database. They allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive file formats are designed to be portable across architectures.

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the “custom” format (`-Fc`) and the “directory” format (`-Fd`). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The “directory” format is the only format that supports parallel dumps.

While running `pg_dump`, one should examine the output for any warnings (printed on standard error), especially in light of the limitations listed below.

## Options

The following command-line options control the content and format of the output.

*dbname*

Specifies the name of the database to be dumped. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

`-a`

`--data-only`

Dump only the data, not the schema (data definitions). Table data, large objects, and sequence values are dumped.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

`-b`

`--blobs`

Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, or `--schema-only` is specified. The `-b` switch is therefore only useful to add large objects to dumps where a specific schema or table has been requested. Note that blobs are considered data and therefore will be included when `--data-only` is used, but not when `--schema-only` is.

`-B`  
`--no-blobs`  
Exclude large objects in the dump.  
  
When both `-b` and `-B` are given, the behavior is to output large objects, when data is being dumped, see the `-b` documentation.

`-c`  
`--clean`  
Output commands to clean (drop) database objects prior to outputting the commands for creating them. (Unless `--if-exists` is also specified, restore might generate some harmless error messages, if any objects were not present in the destination database.)  
  
This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

`-C`  
`--create`  
Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If `--clean` is also specified, the script drops and recreates the target database before reconnecting to it.  
  
This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

`-E encoding`  
`--encoding=encoding`  
Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

`-f file`  
`--file=file`  
Send output to the specified file. This parameter can be omitted for file based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by `pg_dump` and must not exist before.

`-F format`  
`--format=format`  
Selects the format of the output. *format* can be one of the following:

`p`  
`plain`  
Output a plain-text SQL script file (the default).

`c`  
`custom`  
Output a custom-format archive suitable for input into `pg_restore`. Together with the directory output format, this is the most flexible output format in that it allows manual selection and re-ordering of archived items during restore. This format is also compressed by default.

`d`  
`directory`  
Output a directory-format archive suitable for input into `pg_restore`. This will create a directory with one file for each table and blob being dumped, plus a so-called Table of Contents file de-

scribing the dumped objects in a machine-readable format that `pg_restore` can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the `gzip` tool. This format is compressed by default and also supports parallel dumps.

t  
tar

Output a `tar`-format archive suitable for input into `pg_restore`. The `tar` format is compatible with the directory format: extracting a `tar`-format archive produces a valid directory-format archive. However, the `tar` format does not support compression. Also, when using `tar` format the relative order of table data items cannot be changed during restore.

-j *njobs*  
--jobs=*njobs*

Run the dump in parallel by dumping *njobs* tables simultaneously. This option reduces the time of the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

`pg_dump` will open *njobs* + 1 connections to the database, so make sure your `max_connections` setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the `pg_dump` master process requests shared locks on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the master process to be released. Consequently any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the `pg_dump` worker process requests another shared lock using the `NOWAIT` option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so `pg_dump` has no choice but to abort the dump.

For a consistent backup, the database server needs to support synchronized snapshots, a feature that was introduced in PostgreSQL 9.2 for primary servers and 10 for standbys. With this feature, database clients can ensure they see the same data set even though they use different connections. `pg_dump -j` uses multiple database connections; it connects to the database once with the master process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

If you want to run a parallel dump of a pre-9.2 server, you need to make sure that the database content doesn't change from between the time the master connects to the database until the last worker job has connected to the database. The easiest way to do this is to halt any data modifying processes (DDL and DML) accessing the database before starting the backup. You also need to specify the `--no-synchronized-snapshots` parameter when running `pg_dump -j` against a pre-9.2 PostgreSQL server.

-n *schema*  
--schema=*schema*

Dump only schemas matching *schema*; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. Also, the *schema* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see the section called "Patterns"), so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see the section called "Examples".

**Note**

When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

**Note**

Non-schema objects such as blobs are not dumped when `-n` is specified. You can add blobs back to the dump with the `--blobs` switch.

`-N schema`  
`--exclude-schema=schema`

Do not dump any schemas matching the `schema` pattern. The pattern is interpreted according to the same rules as for `-n`. `-N` can be given more than once to exclude schemas matching any of several patterns.

When both `-n` and `-N` are given, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

`-o`  
`--oids`

Dump object identifiers (OIDs) as part of the data for every table. Use this option if your application references the OID columns in some way (e.g., in a foreign key constraint). Otherwise, this option should not be used.

`-O`  
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

`-R`  
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`  
`--schema-only`

Dump only the object definitions (schema), not data.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word “schema” in a different meaning.)

To exclude table data for only a subset of tables in the database, see `--exclude-table-data`.

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t table`  
`--table=table`

Dump only tables with names matching `table`. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple `-t` switches. Also, the `table` parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see the section called “Patterns”), so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see the section called “Examples”.

The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

### Note

When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

### Note

The behavior of the `-t` switch is not entirely upward compatible with pre-8.2 PostgreSQL versions. Formerly, writing `-t tab` would dump all tables named `tab`, but now it just dumps whichever one is visible in your default search path. To get the old behavior you can write `-t '*.tab'`. Also, you must write something like `-t sch.tab` to select a table in a particular schema, rather than the old locution of `-n sch -t tab`.

`-T table`  
`--exclude-table=table`

Do not dump any tables matching the `table` pattern. The pattern is interpreted according to the same rules as for `-t`. `-T` can be given more than once to exclude tables matching any of several patterns.

When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

`-v`  
`--verbose`

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

`-V`  
`--version`

Print the `pg_dump` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`

Prevent dumping of access privileges (grant/revoke commands).

`-Z 0..9`  
`--compress=0..9`

Specify the compression level to use. Zero means no compression. For the custom archive format, this specifies compression of individual table-data segments, and the default is to compress at a moderate level. For plain text output, setting a nonzero compression level causes the entire output file to be compressed, as though it had been fed through gzip; but the default is not to compress. The tar archive format currently does not support compression at all.

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts`  
`--attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

`--disable-dollar-quoting`

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`

This option is relevant only when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-s`, or preferably be careful to start the resulting script as a superuser.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

`--enable-row-security`

This option is relevant only when dumping the contents of a table which has row security. By default, `pg_dump` will set `row_security` to off, to ensure that all data is dumped from the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_dump` to set `row_security` to on instead, allowing the user to dump the parts of the contents of the table that they have access to.

Note that if you use this option currently, you probably also want the dump be in `INSERT` format, as the `COPY FROM` during restore does not support row security.

`--exclude-table-data=table`

Do not dump data for any tables matching the `table` pattern. The pattern is interpreted according to the same rules as for `-t`. `--exclude-table-data` can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see `--schema-only`.

`--if-exists`

Use conditional commands (i.e. add an `IF EXISTS` clause) when cleaning database objects. This option is not valid unless `--clean` is also specified.

`--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore might fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

`--lock-wait-timeout=timeout`

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead fail if unable to lock a table within the specified *timeout*. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. (Allowed formats vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions.)

`--no-publications`

Do not dump publications.

`--no-security-labels`

Do not dump security labels.

`--no-subscriptions`

Do not dump subscriptions.

`--no-sync`

By default, `pg_dump` will wait for all files to be written safely to disk. This option causes `pg_dump` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

`--no-synchronized-snapshots`

This option allows running `pg_dump -j` against a pre-9.2 server, see the documentation of the `-j` parameter for more details.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

`--no-unlogged-table-data`

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data. Data in unlogged tables is always excluded when dumping from a standby server.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dump`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dump` quotes only identifiers that

are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--section=sectionname`

Only dump the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The data section contains actual table data, large-object contents, and sequence values. Post-data items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. Pre-data items include all other data definition items.

`--serializable-deferrable`

Use a `serializable` transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a `serialization_failure`. See Chapter 13 for more information about transaction isolation and concurrency control.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when `pg_dump` is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

`--snapshot=snapshotname`

Use the specified synchronized snapshot when making a dump of the database (see Table 9.82 for more details).

This option is useful when needing to synchronize the dump with a logical replication slot (see Chapter 49) or with a concurrent session.

In the case of a parallel dump, the snapshot name defined by this option is used rather than taking a new snapshot.

`--strict-names`

Require that each schema (`-n/--schema`) and table (`-t/--table`) qualifier match at least one schema/table in the database to be dumped. Note that if none of the schema/table qualifiers find matches, `pg_dump` will generate an error even without `--strict-names`.

This option has no effect on `-N/--exclude-schema`, `-T/--exclude-table`, or `--exclude-table-data`. An exclude pattern failing to match any objects is not considered an error.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly. Also, a dump using `SET SESSION AUTHORIZATION` will certainly require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

`-?`

`--help`

Show help about `pg_dump` command line arguments, and exit.

The following command-line options control the database connection parameters.

`-d dbname`  
`--dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying *dbname* as the first non-option argument on the command line.

If this parameter contains an = sign or starts with a valid URI prefix (`postgresql://` or `postgres://`), it is treated as a *conninfo* string. See Section 34.1 for more information.

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_dump` to prompt for a password before connecting to a database.

This option is never essential, since `pg_dump` will automatically prompt for a password if the server demands password authentication. However, `pg_dump` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dump` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dump`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Environment

`PGDATABASE`  
`PGHOST`  
`PGOPTIONS`  
`PGPORT`  
`PGUSER`

Default connection parameters.

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Diagnostics

`pg_dump` internally executes `SELECT` statements. If you have problems running `pg_dump`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

The database activity of `pg_dump` is normally collected by the statistics collector. If this is undesirable, you can set parameter `track_counts` to `false` via `PGOPTIONS` or the `ALTER USER` command.

## Notes

If your database cluster has any local additions to the `template1` database, be careful to restore the output of `pg_dump` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When a data-only dump is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to disable triggers on user tables before inserting the data, and then commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

The dump file produced by `pg_dump` does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure optimal performance; see Section 25.1.3 and Section 25.1.6 for more information. The dump file also does not contain any `ALTER DATABASE ... SET` commands; these settings are dumped by `pg_dumpall`, along with database users and other installation-wide settings.

Because `pg_dump` is used to transfer data to newer versions of , the output of `pg_dump` can be expected to load into server versions newer than `pg_dump`'s version. `pg_dump` can also dump from servers older than its own version. (Currently, servers back to version 8.0 are supported.) However, `pg_dump` cannot dump from servers newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump`'s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different PostgreSQL versions.

When dumping logical replication subscriptions, `pg_dump` will generate `CREATE SUBSCRIPTION` commands that use the `NOCONNECT` option, so that restoring the subscription does not make remote connections for creating a replication slot or for initial table copy. That way, the dump can be restored without requiring network access to the remote servers. It is then up to the user to reactivate the subscriptions in a suitable way. If the involved hosts have changed, the connection information might have to be changed. It might also be appropriate to truncate the target tables before initiating a new full table copy.

## Examples

To dump a database called `mydb` into a SQL-script file:

```
$ pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```
$ psql -d newdb -f db.sql
```

To dump a database into a custom-format archive file:

```
$ pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```
$ pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```
$ pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb`:

```
$ pg_restore -d newdb db.dump
```

To dump a single table named `mytab`:

```
$ pg_dump -t mytab mydb > db.sql
```

To dump all tables whose names start with `emp` in the `detroit` schema, except for the table named `employee_log`:

```
$ pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
```

To dump all schemas whose names start with `east` or `west` and end in `gsm`, excluding any schemas whose names contain the word `test`:

```
$ pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
```

The same, using regular expression notation to consolidate the switches:

```
$ pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
```

To dump all database objects except for tables whose names begin with `ts_`:

```
$ pg_dump -T 'ts_*' mydb > db.sql
```

To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case (see the section called “Patterns”). But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like

```
$ pg_dump -t "\"MixedCaseName\"" mydb > mytab.sql
```

---

# pg\_dumpall

pg\_dumpall — extract a database cluster into a script file

## Synopsis

```
pg_dumpall [connection-option...] [option...]
```

## Description

pg\_dumpall is a utility for writing out (“dumping”) all databases of a cluster into one script file. The script file contains SQL commands that can be used as input to psql to restore the databases. It does this by calling pg\_dump for each database in a cluster. pg\_dumpall also dumps global objects that are common to all databases. (pg\_dump does not save these objects.) This currently includes information about database users and groups, tablespaces, and properties such as access permissions that apply to databases as a whole.

Since pg\_dumpall reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add users and groups, and to create databases.

The SQL script will be written to the standard output. Use the [-f|file] option or shell operators to redirect it into a file.

pg\_dumpall needs to connect several times to the server (once per database). If you use password authentication it will ask for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 34.15 for more information.

## Options

The following command-line options control the content and format of the output.

- a  
--data-only  
Dump only the data, not the schema (data definitions).
- c  
--clean  
Include SQL commands to clean (drop) databases before recreating them. DROP commands for roles and tablespaces are added as well.
- f *filename*  
--file=*filename*  
Send output to the specified file. If this is omitted, the standard output is used.
- g  
--globals-only  
Dump only global objects (roles and tablespaces), no databases.
- o  
--oids  
Dump object identifiers (OIDs) as part of the data for every table. Use this option if your application references the OID columns in some way (e.g., in a foreign key constraint). Otherwise, this option should not be used.

`-O`  
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dumpall` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

`-r`  
`--roles-only`

Dump only roles, no databases or tablespaces.

`-s`  
`--schema-only`

Dump only the object definitions (schema), not data.

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t`  
`--tablespaces-only`

Dump only tablespaces, no databases or roles.

`-v`  
`--verbose`

Specifies verbose mode. This will cause `pg_dumpall` to output start/stop times to the dump file, and progress messages to standard error. It will also enable verbose output in `pg_dump`.

`-V`  
`--version`

Print the `pg_dumpall` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`

Prevent dumping of access privileges (grant/revoke commands).

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts`  
`--attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non- databases.

`--disable-dollar-quoting`

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

**--disable-triggers**

This option is relevant only when creating a data-only dump. It instructs `pg_dumpall` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

**--if-exists**

Use conditional commands (i.e. add an `IF EXISTS` clause) to clean databases and other objects. This option is not valid unless `--clean` is also specified.

**--inserts**

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non- databases. Note that the restore might fail altogether if you have rearranged column order. The `--column-inserts` option is safer, though even slower.

**--lock-wait-timeout=*timeout***

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified *timeout*. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. Allowed values vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions since 7.3. This option is ignored when dumping from a pre-7.3 server.

**--no-publications**

Do not dump publications.

**--no-role-passwords**

Do not dump passwords for roles. When restored, roles will have a null password, and password authentication will always fail until the password is set. Since password values aren't needed when this option is specified, the role information is read from the catalog view `pg_roles` instead of `pg_authid`. Therefore, this option also helps if access to `pg_authid` is restricted by some security policy.

**--no-security-labels**

Do not dump security labels.

**--no-subscriptions**

Do not dump subscriptions.

**--no-sync**

By default, `pg_dumpall` will wait for all files to be written safely to disk. This option causes `pg_dumpall` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the dump corrupt. Generally, this option is useful for testing but should not be used when dumping data from production installation.

**--no-tablespaces**

Do not output commands to create tablespaces nor select tablespaces for objects. With this option, all objects will be created in whichever tablespace is the default during restore.

**--no-unlogged-table-data**

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from `pg_dumpall`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dumpall` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly.

`-?`

`--help`

Show help about `pg_dumpall` command line arguments, and exit.

The following command-line options control the database connection parameters.

`-d connstr`

`--dbname=connstr`

Specifies parameters used to connect to the server, as a connection string. See Section 34.1.1 for more information.

The option is called `--dbname` for consistency with other client applications, but because `pg_dumpall` needs to connect to many databases, database name in the connection string will be ignored. Use `-l` option to specify the name of the database used to dump global objects and to discover what other databases should be dumped.

`-h host`

`--host=host`

Specifies the host name of the machine on which the database server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-l dbname`

`--database=dbname`

Specifies the name of the database to connect to for dumping global objects and discovering what other databases should be dumped. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_dumpall` to prompt for a password before connecting to a database.

This option is never essential, since `pg_dumpall` will automatically prompt for a password if the server demands password authentication. However, `pg_dumpall` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Note that the password prompt will occur again for each database to be dumped. Usually, it's better to set up a `~/.pgpass` file than to rely on manual password entry.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dumpall` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dumpall`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Environment

`PGHOST`  
`PGOPTIONS`  
`PGPORT`  
`PGUSER`

Default connection parameters

This utility, like most other utilities, also uses the environment variables supported by `libpq` (see Section 34.14).

## Notes

Since `pg_dumpall` calls `pg_dump` internally, some diagnostic messages will refer to `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each database so the optimizer has useful statistics. You can also run `vacuumdb -a -z` to analyze all databases.

`pg_dumpall` requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

## Examples

To dump all databases:

```
$ pg_dumpall > db.out
```

To reload database(s) from this file, you can use:

```
$ psql -f db.out postgres
```

(It is not important to which database you connect here since the script file created by `pg_dumpall` will contain the appropriate commands to create and connect to the saved databases.)

## See Also

Check `pg_dump` for details on possible error conditions.

---

# pg\_isready

pg\_isready — check the connection status of a server

## Synopsis

```
pg_isready [connection-option...] [option...]
```

## Description

pg\_isready is a utility for checking the connection status of a database server. The exit status specifies the result of the connection check.

## Options

-d *dbname*

--dbname=*dbname*

Specifies the name of the database to connect to.

If this parameter contains an = sign or starts with a valid URI prefix (`postgresql://` or `postgres://`), it is treated as a *conninfo* string. See Section 34.1.1 for more information.

-h *hostname*

--host=*hostname*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

-p *port*

--port=*port*

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

-q

--quiet

Do not display status message. This is useful when scripting.

-t *seconds*

--timeout=*seconds*

The maximum number of seconds to wait when attempting connection before returning that the server is not responding. Setting to 0 disables. The default is 3 seconds.

-U *username*

--username=*username*

Connect to the database as the user *username* instead of the default.

-V

--version

Print the pg\_isready version and exit.

-?

--help

Show help about pg\_isready command line arguments, and exit.

## Exit Status

`pg_isready` returns 0 to the shell if the server is accepting connections normally, 1 if the server is rejecting connections (for example during startup), 2 if there was no response to the connection attempt, and 3 if no attempt was made (for example due to invalid parameters).

## Environment

`pg_isready`, like most other utilities, also uses the environment variables supported by `libpq` (see Section 34.14).

## Notes

It is not necessary to supply correct user name, password, or database name values to obtain the server status; however, if incorrect values are provided, the server will log a failed connection attempt.

## Examples

Standard Usage:

```
$ pg_isready  
/tmp:5432 - accepting connections  
$ echo $?  
0
```

Running with connection parameters to a cluster in startup:

```
$ pg_isready -h localhost -p 5433  
localhost:5433 - rejecting connections  
$ echo $?  
1
```

Running with connection parameters to a non-responsive cluster:

```
$ pg_isready -h someremotehost  
someremotehost:5432 - no response  
$ echo $?  
2
```

---

# pg\_receivewal

pg\_receivewal — stream write-ahead logs from a server

## Synopsis

```
pg_receivewal [option...]
```

## Description

pg\_receivewal is used to stream the write-ahead log from a running cluster. The write-ahead log is streamed using the streaming replication protocol, and is written to a local directory of files. This directory can be used as the archive location for doing a restore using point-in-time recovery (see Section 26.3).

pg\_receivewal streams the write-ahead log in real time as it's being generated on the server, and does not wait for segments to complete like archive\_command does. For this reason, it is not necessary to set archive\_timeout when using pg\_receivewal.

Unlike the WAL receiver of a standby server, pg\_receivewal by default flushes WAL data only when a WAL file is closed. The option `--synchronous` must be specified to flush WAL data in real time.

The write-ahead log is streamed over a regular connection and uses the replication protocol. The connection must be made with a superuser or a user having `REPLICATION` permissions (see Section 22.2), and `pg_hba.conf` must permit the replication connection. The server must also be configured with `max_wal_senders` set high enough to leave at least one session available for the stream.

If the connection is lost, or if it cannot be initially established, with a non-fatal error, pg\_receivewal will retry the connection indefinitely, and reestablish streaming as soon as possible. To avoid this behavior, use the `-n` parameter.

## Options

`-D directory`

`--directory=directory`

Directory to write the output to.

This parameter is required.

`--if-not-exists`

Do not error out when `--create-slot` is specified and a slot with the specified name already exists.

`-n`

`--no-loop`

Don't loop on connection errors. Instead, exit right away with an error.

`-s interval`

`--status-interval=interval`

Specifies the number of seconds between status packets sent back to the server. This allows for easier monitoring of the progress from server. A value of zero disables the periodic status updates completely, although an update will still be sent when requested by the server, to avoid timeout disconnect. The default value is 10 seconds.

`-S slotname`

`--slot=slotname`

Require pg\_receivewal to use an existing replication slot (see Section 27.2.6). When this option is used, pg\_receivewal will report a flush position to the server, indicating when each segment has been synchronized to disk so that the server can remove that segment if it is not otherwise needed.

When the replication client of `pg_receivewal` is configured on the server as a synchronous standby, then using a replication slot will report the flush position to the server, but only when a WAL file is closed. Therefore, that configuration will cause transactions on the primary to wait for a long time and effectively not work satisfactorily. The option `--synchronous` (see below) must be specified in addition to make this work correctly.

`--synchronous`

Flush the WAL data to disk immediately after it has been received. Also send a status packet back to the server immediately after flushing, regardless of `--status-interval`.

This option should be specified if the replication client of `pg_receivewal` is configured on the server as a synchronous standby, to ensure that timely feedback is sent to the server.

`-v`

`--verbose`

Enables verbose mode.

`-Z level`

`--compress=level`

Enables gzip compression of write-ahead logs, and specifies the compression level (0 through 9, 0 being no compression and 9 being best compression). The suffix `.gz` will automatically be added to all filenames.

The following command-line options control the database connection parameters.

`-d connstr`

`--dbname=connstr`

Specifies parameters used to connect to the server, as a connection string. See Section 34.1.1 for more information.

The option is called `--dbname` for consistency with other client applications, but because `pg_receivewal` doesn't connect to any particular database in the cluster, database name in the connection string will be ignored.

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_receivewal` to prompt for a password before connecting to a database.

This option is never essential, since `pg_receivewal` will automatically prompt for a password if the server demands password authentication. However, `pg_receivewal` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`pg_receivewal` can perform one of the two following actions in order to control physical replication slots:

`--create-slot`

Create a new physical replication slot with the name specified in `--slot`, then exit.

`--drop-slot`

Drop the replication slot with the name specified in `--slot`, then exit.

Other options are also available:

`-V`  
`--version`

Print the `pg_receivewal` version and exit.

`-?`  
`--help`

Show help about `pg_receivewal` command line arguments, and exit.

## Environment

This utility, like most other utilities, uses the environment variables supported by `libpq` (see Section 34.14).

## Notes

When using `pg_receivewal` instead of `archive_command` as the main WAL backup method, it is strongly recommended to use replication slots. Otherwise, the server is free to recycle or remove write-ahead log files before they are backed up, because it does not have any information, either from `archive_command` or the replication slots, about how far the WAL stream has been archived. Note, however, that a replication slot will fill up the server's disk space if the receiver does not keep up with fetching the WAL data.

## Examples

To stream the write-ahead log from the server at `mydbserver` and store it in the local directory `/usr/local/pgsql/archive`:

```
$ pg_receivewal -h mydbserver -D /usr/local/pgsql/archive
```

## See Also

`pg_basebackup`

---

# pg\_recvlogical

pg\_recvlogical — control logical decoding streams

## Synopsis

pg\_recvlogical [*option...*]

## Description

pg\_recvlogical controls logical decoding replication slots and streams data from such replication slots.

It creates a replication-mode connection, so it is subject to the same constraints as pg\_receivewal, plus those for logical replication (see Chapter 49).

pg\_recvlogical has no equivalent to the logical decoding SQL interface's peek and get modes. It sends replay confirmations for data lazily as it receives it and on clean exit. To examine pending data on a slot without consuming it, use pg\_logical\_slot\_peek\_changes.

## Options

At least one of the following options must be specified to select an action:

`--create-slot`

Create a new logical replication slot with the name specified by `--slot`, using the output plugin specified by `--plugin`, for the database specified by `--dbname`.

`--drop-slot`

Drop the replication slot with the name specified by `--slot`, then exit.

`--start`

Begin streaming changes from the logical replication slot specified by `--slot`, continuing until terminated by a signal. If the server side change stream ends with a server shutdown or disconnect, retry in a loop unless `--no-loop` is specified.

The stream format is determined by the output plugin specified when the slot was created.

The connection must be to the same database used to create the slot.

`--create-slot` and `--start` can be specified together. `--drop-slot` cannot be combined with another action.

The following command-line options control the location and format of the output and other replication behavior:

`-E lsn`

`--endpos=lsn`

In `--start` mode, automatically stop replication and exit with normal exit status 0 when receiving reaches the specified LSN. If specified when not in `--start` mode, an error is raised.

If there's a record with LSN exactly equal to `lsn`, the record will be output.

The `--endpos` option is not aware of transaction boundaries and may truncate output partway through a transaction. Any partially output transaction will not be consumed and will be replayed again when the slot is next read from. Individual messages are never truncated.

`-f filename`

`--file=filename`

Write received and decoded transaction data into this file. Use `-` for stdout.

`-F interval_seconds`  
`--fsync-interval=interval_seconds`

Specifies how often `pg_recvlogical` should issue `fsync()` calls to ensure the output file is safely flushed to disk.

The server will occasionally request the client to perform a flush and report the flush position to the server. This setting is in addition to that, to perform flushes more frequently.

Specifying an interval of 0 disables issuing `fsync()` calls altogether, while still reporting progress to the server. In this case, data could be lost in the event of a crash.

`-I lsn`  
`--startpos=lsn`

In `--start` mode, start replication from the given LSN. For details on the effect of this, see the documentation in Chapter 49 and Section 53.4. Ignored in other modes.

`--if-not-exists`

Do not error out when `--create-slot` is specified and a slot with the specified name already exists.

`-n`  
`--no-loop`

When the connection to the server is lost, do not retry in a loop, just exit.

`-o name[=value]`  
`--option=name[=value]`

Pass the option `name` to the output plugin with, if specified, the option value `value`. Which options exist and their effects depends on the used output plugin.

`-P plugin`  
`--plugin=plugin`

When creating a slot, use the specified logical decoding output plugin. See Chapter 49. This option has no effect if the slot already exists.

`-s interval_seconds`  
`--status-interval=interval_seconds`

This option has the same effect as the option of the same name in `pg_receivewal`. See the description there.

`-S slot_name`  
`--slot=slot_name`

In `--start` mode, use the existing logical replication slot named `slot_name`. In `--create-slot` mode, create the slot with this name. In `--drop-slot` mode, delete the slot with this name.

`-v`  
`--verbose`

Enables verbose mode.

The following command-line options control the database connection parameters.

`-d database`  
`--dbname=database`

The database to connect to. See the description of the actions for what this means in detail. This can be a libpq connection string; see Section 34.1.1 for more information. Defaults to user name.

`-h hostname-or-ip`  
`--host=hostname-or-ip`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U user`  
`--username=user`

User name to connect as. Defaults to current operating system user name.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_recvlogical` to prompt for a password before connecting to a database.

This option is never essential, since `pg_recvlogical` will automatically prompt for a password if the server demands password authentication. However, `pg_recvlogical` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

The following additional options are available:

`-V`  
`--version`

Print the `pg_recvlogical` version and exit.

`-?`  
`--help`

Show help about `pg_recvlogical` command line arguments, and exit.

## Environment

This utility, like most other utilities, uses the environment variables supported by `libpq` (see Section 34.14).

## Examples

See Section 49.1 for an example.

## pg\_restore

`pg_restore` — restore a database from an archive file created by `pg_dump`

### Synopsis

```
pg_restore [connection-option...] [option...] [filename]
```

### Description

`pg_restore` is a utility for restoring a database from an archive created by `pg_dump` in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive files are designed to be portable across architectures.

`pg_restore` can operate in two modes. If a database name is specified, `pg_restore` connects to that database and restores archive contents directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. This script output is equivalent to the plain text output format of `pg_dump`. Some of the options controlling the output are therefore analogous to `pg_dump` options.

Obviously, `pg_restore` cannot restore information that is not present in the archive file. For instance, if the archive was made using the “dump data as `INSERT` commands” option, `pg_restore` will not be able to load the data using `COPY` statements.

### Options

`pg_restore` accepts the following command line arguments.

*filename*

Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

`-a`

`--data-only`

Restore only the data, not the schema (data definitions). Table data, large objects, and sequence values are restored, if present in the archive.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

`-c`

`--clean`

Clean (drop) database objects before recreating them. (Unless `--if-exists` is used, this might generate some harmless error messages, if any objects were not present in the destination database.)

`-C`

`--create`

Create the database before restoring into it. If `--clean` is also specified, drop and recreate the target database before connecting to it.

When this option is used, the database named with `-d` is used only to issue the initial `DROP DATABASE` and `CREATE DATABASE` commands. All data is restored into the database name that appears in the archive.

`-d dbname`

`--dbname=dbname`

Connect to database *dbname* and restore directly into the database.

---

`-e`  
`--exit-on-error`

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

`-f filename`  
`--file=filename`

Specify output file for generated script, or for the listing when used with `-l`. Default is the standard output.

`-F format`  
`--format=format`

Specify format of the archive. It is not necessary to specify the format, since `pg_restore` will determine the format automatically. If specified, it can be one of the following:

`c`  
custom

The archive is in the custom format of `pg_dump`.

`d`  
directory

The archive is a directory archive.

`t`  
tar

The archive is a `tar` archive.

`-I index`  
`--index=index`

Restore definition of named index only. Multiple indexes may be specified with multiple `-I` switches.

`-j number-of-jobs`  
`--jobs=number-of-jobs`

Run the most time-consuming parts of `pg_restore` — those which load data, create indexes, or create constraints — using multiple concurrent jobs. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom and directory archive formats are supported with this option. The input must be a regular file or directory (not, for example, a pipe). This option is ignored when emitting a script rather than connecting directly to a database server. Also, multiple jobs cannot be used together with the option `--single-transaction`.

`-l`  
`--list`

List the table of contents of the archive. The output of this operation can be used as input to the `-L` option. Note that if filtering switches such as `-n` or `-t` are used with `-l`, they will restrict the items listed.

---

---

`-L list-file`  
`--use-list=list-file`

Restore only those archive elements that are listed in *list-file*, and restore them in the order they appear in the file. Note that if filtering switches such as `-n` or `-t` are used with `-L`, they will further restrict the items restored.

*list-file* is normally created by editing the output of a previous `-l` operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (;) at the start of the line. See below for examples.

`-n schema`  
`--schema=schema`

Restore only objects that are in the named schema. Multiple schemas may be specified with multiple `-n` switches. This can be combined with the `-t` option to restore just a specific table.

`-N schema`  
`--exclude-schema=schema`

Do not restore objects that are in the named schema. Multiple schemas to be excluded may be specified with multiple `-N` switches.

When both `-n` and `-N` are given for the same schema name, the `-N` switch wins and the schema is excluded.

`-O`  
`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

`-P function-name(argtype [, ...])`  
`--function=function-name(argtype [, ...])`

Restore the named function only. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents. Multiple functions may be specified with multiple `-P` switches.

`-R`  
`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`  
`--schema-only`

Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word "schema" in a different meaning.)

`-S username`  
`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is relevant only if `--disable-triggers` is used.

`-t table`  
`--table=table`

Restore definition and/or data of only the named table. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple `-t` switches. This option can be combined with the `-n` option to specify table(s) in a particular schema.

### Note

When `-t` is specified, `pg_restore` makes no attempt to restore any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that a specific-table restore into a clean database will succeed.

### Note

This flag does not behave identically to the `-t` flag of `pg_dump`. There is not currently any provision for wild-card matching in `pg_restore`, nor can you include a schema name within its `-t`.

### Note

In versions prior to 9.6, this flag matched only tables, not any other type of relation.

`-T trigger`  
`--trigger=trigger`

Restore named trigger only. Multiple triggers may be specified with multiple `-T` switches.

`-v`  
`--verbose`

Specifies verbose mode.

`-V`  
`--version`

Print the `pg_restore` version and exit.

`-x`  
`--no-privileges`  
`--no-acl`

Prevent restoration of access privileges (grant/revoke commands).

`-1`  
`--single-transaction`

Execute the restore as a single transaction (that is, wrap the emitted commands in `BEGIN/COMMIT`). This ensures that either all the commands complete successfully, or no changes are applied. This option implies `--exit-on-error`.

`--disable-triggers`

This option is relevant only when performing a data-only restore. It instructs `pg_restore` to execute commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if

you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So you should also specify a superuser name with `-s` or, preferably, run `pg_restore` as a superuser.

`--enable-row-security`

This option is relevant only when restoring the contents of a table which has row security. By default, `pg_restore` will set `row_security` to `off`, to ensure that all data is restored in to the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs `pg_restore` to set `row_security` to `on` instead, allowing the user to attempt to restore the contents of the table with row security enabled. This might still fail if the user does not have the right to insert the rows from the dump into the table.

Note that this option currently also requires the dump be in `INSERT` format, as `COPY FROM` does not support row security.

`--if-exists`

Use conditional commands (i.e. add an `IF EXISTS` clause) when cleaning database objects. This option is not valid unless `--clean` is also specified.

`--no-data-for-failed-tables`

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful if the target database already contains the desired table contents. For example, auxiliary tables for extensions such as PostGIS might already be loaded in the target database; specifying this option prevents duplicate or obsolete data from being loaded into them.

This option is effective only when restoring directly into a database, not when producing SQL script output.

`--no-publications`

Do not output commands to restore publications, even if the archive contains them.

`--no-security-labels`

Do not output commands to restore security labels, even if the archive contains them.

`--no-subscriptions`

Do not output commands to restore subscriptions, even if the archive contains them.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

`--section=sectionname`

Only restore the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to restore all sections.

The data section contains actual table data as well as large-object definitions. Post-data items consist of definitions of indexes, triggers, rules and constraints other than validated check constraints. Pre-data items consist of all other data definition items.

`--strict-names`

Require that each schema (`-n/--schema`) and table (`-t/--table`) qualifier match at least one schema/table in the backup file.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly.

`-?`

`--help`

Show help about `pg_restore` command line arguments, and exit.

`pg_restore` also accepts the following command line arguments for connection parameters:

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

`-U username`

`--username=username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`

`--password`

Force `pg_restore` to prompt for a password before connecting to a database.

This option is never essential, since `pg_restore` will automatically prompt for a password if the server demands password authentication. However, `pg_restore` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

`--role=rolename`

Specifies a role name to be used to perform the restore. This option causes `pg_restore` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_restore`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

## Environment

`PGHOST`

`PGOPTIONS`

`PGPORT`

`PGUSER`

Default connection parameters

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14). However, it does not read `PGDATABASE` when a database name is not supplied.

## Diagnostics

When a direct database connection is specified using the `-d` option, `pg_restore` internally executes SQL statements. If you have problems running `pg_restore`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

If your installation has any local additions to the `template1` database, be careful to load the output of `pg_restore` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

The limitations of `pg_restore` are detailed below.

- When restoring data to a pre-existing table and the option `--disable-triggers` is used, `pg_restore` emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.
- `pg_restore` cannot restore large objects selectively; for instance, only those for a specific table. If an archive contains large objects, then all large objects will be restored, or none of them if they are excluded via `-L`, `-t`, or other options.

See also the `pg_dump` documentation for details on limitations of `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each restored table so the optimizer has useful statistics; see Section 25.1.3 and Section 25.1.6 for more information.

## Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
$ pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
$ dropdb mydb
$ pg_restore -C -d postgres db.dump
```

The database named in the `-d` switch can be any database existing in the cluster; `pg_restore` only uses it to issue the `CREATE DATABASE` command for `mydb`. With `-C`, data is always restored into the database name that appears in the dump file.

To reload the dump into a new database called `newdb`:

```
$ createdb -T template0 newdb
$ pg_restore -d newdb db.dump
```

Notice we don't use `-C`, and instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty.

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
$ pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, e.g.:

```
;
```

```
; Archive created at Mon Sep 14 13:55:39 2009
; dbname: DBDEMOS
; TOC Entries: 81
; Compression: 9
; Dump Version: 1.10-0
; Format: CUSTOM
; Integer: 4 bytes
; Offset: 8 bytes
; Dumped from database version: 8.3.5
; Dumped by pg_dump version: 8.3.8
;
;
; Selected TOC Entries:
;
3; 2615 2200 SCHEMA - public pasha
1861; 0 0 COMMENT - SCHEMA public pasha
1862; 0 0 ACL - public pasha
317; 1247 17715 TYPE public composite pasha
319; 1247 25899 DOMAIN public domain0 pasha
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item.

Lines in the file can be commented out, deleted, and reordered. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
$ pg_restore -L db.list db.dump
```

# psql

psql — interactive terminal

## Synopsis

```
psql [option...] [dbname [username]]
```

## Description

psql is a terminal-based front-end to . It enables you to type in queries interactively, issue them to , and see the query results. Alternatively, input can be from a file or from command line arguments. In addition, psql provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

## Options

-a  
--echo-all

Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable `ECHO` to `all`.

-A  
--no-align

Switches to unaligned output mode. (The default output mode is otherwise aligned.) This is equivalent to `\pset format unaligned`.

-b  
--echo-errors

Print failed SQL commands to standard error output. This is equivalent to setting the variable `ECHO` to `errors`.

-c *command*  
--command=*command*

Specifies that psql is to execute the given command string, *command*. This option can be repeated and combined in any order with the `-f` option. When either `-c` or `-f` is specified, psql does not read commands from standard input; instead it terminates after processing all the `-c` and `-f` options in sequence.

*command* must be either a command string that is completely parsable by the server (i.e., it contains no psql-specific features), or a single backslash command. Thus you cannot mix SQL and psql meta-commands within a `-c` option. To achieve that, you could use repeated `-c` options or pipe the string into psql, for example:

```
psql -c '\x' -c 'SELECT * FROM foo;'
```

or

```
echo '\x \\ SELECT * FROM foo;' | psql
```

(`\\` is the separator meta-command.)

Each SQL command string passed to `-c` is sent to the server as a single query. Because of this, the server executes it as a single transaction even if the string contains multiple SQL commands, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. Also, psql only prints the result of the last SQL command in the string. This is different

from the behavior when the same string is read from a file or fed to psql's standard input, because then psql sends each SQL command separately.

Because of this behavior, putting more than one command in a single `-c` string often has unexpected results. It's better to use repeated `-c` commands or feed multiple commands to psql's standard input, either using `echo` as illustrated above, or via a shell here-document, for example:

```
psql <<EOF
\x
SELECT * FROM foo;
EOF
```

`-d dbname`

`--dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying *dbname* as the first non-option argument on the command line.

If this parameter contains an `=` sign or starts with a valid URI prefix (`postgresql://` or `postgres://`), it is treated as a *conninfo* string. See Section 34.1.1 for more information.

`-e`

`--echo-queries`

Copy all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable `ECHO` to `queries`.

`-E`

`--echo-hidden`

Echo the actual queries generated by `\d` and other backslash commands. You can use this to study psql's internal operations. This is equivalent to setting the variable `ECHO_HIDDEN` to `on`.

`-f filename`

`--file=filename`

Read commands from the file *filename*, rather than standard input. This option can be repeated and combined in any order with the `-c` option. When either `-c` or `-f` is specified, psql does not read commands from standard input; instead it terminates after processing all the `-c` and `-f` options in sequence. Except for that, this option is largely equivalent to the meta-command `\i`.

If *filename* is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note however that Readline is not used in this case (much as if `-n` had been specified).

Using this option is subtly different from writing `psql < filename`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

`-F separator`

`--field-separator=separator`

Use *separator* as the field separator for unaligned output. This is equivalent to `\pset fieldsep` or `\f`.

`-h hostname`

`--host=hostname`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

`-H`  
`--html`

Turn on HTML tabular output. This is equivalent to `\pset format html` or the `\H` command.

`-l`  
`--list`

List all available databases, then exit. Other non-connection options are ignored. This is similar to the meta-command `\list`.

`-L filename`  
`--log-file=filename`

Write all query output into file *filename*, in addition to the normal output destination.

`-n`  
`--no-readline`

Do not use Readline for line editing and do not use the command history. This can be useful to turn off tab expansion when cutting and pasting.

`-o filename`  
`--output=filename`

Put all query output into file *filename*. This is equivalent to the command `\o`.

`-p port`  
`--port=port`

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

`-P assignment`  
`--pset=assignment`

Specifies printing options, in the style of `\pset`. Note that here you have to separate name and value with an equal sign instead of a space. For example, to set the output format to LaTeX, you could write `-P format=latex`.

`-q`  
`--quiet`

Specifies that psql should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option. This is equivalent to setting the variable `QUIET` to `on`.

`-R separator`  
`--record-separator=separator`

Use *separator* as the record separator for unaligned output. This is equivalent to `\pset recordsep`.

`-s`  
`--single-step`

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

`-S`  
`--single-line`

Runs in single-line mode where a newline terminates an SQL command, as a semicolon does.

## Note

This mode is provided for those who insist on it, but you are not necessarily encouraged to use it. In particular, if you mix SQL and meta-commands on a line the order of execution might not always be clear to the inexperienced user.

- `-t`  
`--tuples-only`  
 Turn off printing of column names and result row count footers, etc. This is equivalent to `\t` or `\pset tuples_only`.
- `-T table_options`  
`--table-attr=table_options`  
 Specifies options to be placed within the HTML `table` tag. See `\pset tableattr` for details.
- `-U username`  
`--username=username`  
 Connect to the database as the user `username` instead of the default. (You must have permission to do so, of course.)
- `-v assignment`  
`--set=assignment`  
`--variable=assignment`  
 Perform a variable assignment, like the `\set` meta-command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during command line processing, so variables that reflect connection state will get overwritten later.
- `-V`  
`--version`  
 Print the psql version and exit.
- `-w`  
`--no-password`  
 Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.  
 Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.
- `-W`  
`--password`  
 Force psql to prompt for a password before connecting to a database.  
 This option is never essential, since psql will automatically prompt for a password if the server demands password authentication. However, psql will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.  
 Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.
- `-x`  
`--expanded`  
 Turn on the expanded table formatting mode. This is equivalent to `\x` or `\pset expanded`.

-X,  
--no-psqlrc

Do not read the start-up file (neither the system-wide `psqlrc` file nor the user's `~/.psqlrc` file).

-z  
--field-separator-zero

Set the field separator for unaligned output to a zero byte. This is equivalent to `\pset fieldsep_zero`.

-0  
--record-separator-zero

Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with `xargs -0`. This is equivalent to `\pset recordsep_zero`.

-1  
--single-transaction

This option can only be used in combination with one or more `-c` and/or `-f` options. It causes `psql` to issue a `BEGIN` command before the first such option and a `COMMIT` command after the last one, thereby wrapping all the commands into a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

If the commands themselves contain `BEGIN`, `COMMIT`, or `ROLLBACK`, this option will not have the desired effects. Also, if an individual command cannot be executed inside a transaction block, specifying this option will cause the whole transaction to fail.

-?  
--help[=*topic*]

Show help about `psql` and exit. The optional *topic* parameter (defaulting to `options`) selects which part of `psql` is explained: `commands` describes `psql`'s backslash commands; `options` describes the command-line options that can be passed to `psql`; and `variables` shows help about `psql` configuration variables.

## Exit Status

`psql` returns 0 to the shell if it finished normally, 1 if a fatal error of its own occurs (e.g. out of memory, file not found), 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

## Usage

### Connecting to a Database

`psql` is a regular client application. In order to connect to a database you need to know the name of your target database, the host name and port number of the server, and what user name you want to connect as. `psql` can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, `psql` will connect via a Unix-domain socket to a server on the local host, or via TCP/IP to `localhost` on machines that don't have Unix-domain sockets. The default port number is determined at compile time. Since the database server uses the same default, you will not have to specify the port in most cases. The default user name is your operating-system user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults aren't quite right, you can save yourself some typing by setting the environment variables `PGDATABASE`, `PGHOST`, `PGPORT` and/or `PGUSER` to appropriate values. (For additional environment variables, see Section 34.14.) It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. See Section 34.15 for more information.

An alternative way to specify connection parameters is in a *conninfo* string or a URI, which is used instead of a database name. This mechanism give you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
$ psql postgresql://dbmaster:5433/mydb?sslmode=require
```

This way you can also use LDAP for connection parameter lookup as described in Section 34.17. See Section 34.1.2 for more information on all the available connection options.

If the connection could not be made for any reason (e.g., insufficient privileges, server is not running on the targeted host, etc.), psql will return an error and terminate.

If both standard input and standard output are a terminal, then psql sets the client encoding to “auto”, which will detect the appropriate client encoding from the locale settings (LC\_CTYPE environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable PGCLIENTENCODING.

## Entering SQL Commands

In normal operation, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string =>. For example:

```
$ psql testdb
psql (10.1.1)
Type "help" for help.

testdb=>
```

At the prompt, the user can type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

Whenever a command is executed, psql also polls for asynchronous notification events generated by LISTEN and NOTIFY.

While C-style block comments are passed to the server for processing and removal, SQL-standard comments are removed by psql.

## Meta-Commands

Anything you enter in psql that begins with an unquoted backslash is a psql meta-command that is processed by psql itself. These commands make psql more useful for administration or scripting. Meta-commands are often called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace in an argument you can quote it with single quotes. To include a single quote in an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \b (backspace), \r (carriage return), \f (form feed), \digits (octal), and \xdigits (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

If an unquoted colon (:) followed by a psql variable name appears within an argument, it is replaced by the variable's value, as described in the section called “SQL Interpolation”. The forms : 'variable\_name' and : "variable\_name" described there work as well.

Within an argument, text that is enclosed in backquotes (`) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text. Within the text enclosed in backquotes, no special quoting or other processing occurs, except

that appearances of `:variable_name` where `variable_name` is a psql variable name are replaced by the variable's value. Also, appearances of `:'variable_name'` are replaced by the variable's value suitably quoted to become a single shell command argument. (The latter form is almost always preferable, unless you are very sure of what is in the variable.) Because carriage return and line feed characters cannot be safely quoted on all platforms, the `:'variable_name'` form prints an error message and does not substitute the variable value when such characters appear in the value.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird" name"` becomes `A weird" name`.

Parsing for arguments stops at the end of the line, or when another unquoted backslash is found. An unquoted backslash is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Many of the meta-commands act on the *current query buffer*. This is simply a buffer holding whatever SQL command text has been typed but not yet sent to the server for execution. This will include previous input lines as well as any text appearing before the meta-command on the same line.

The following meta-commands are defined:

`\a`

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See `\pset` for a more general solution.

`\c` or `\connect` [ `-reuse-previous=on/off` ] [ `dbname` [ `username` ] [ `host` ] [ `port` ] | `conninfo` ]

Establishes a new connection to a server. The connection parameters to use can be specified either using a positional syntax, or using `conninfo` connection strings as detailed in Section 34.1.1.

Where the command omits database name, user, host, or port, the new connection can reuse values from the previous connection. By default, values from the previous connection are reused except when processing a `conninfo` string. Passing a first argument of `-reuse-previous=on` or `-reuse-previous=off` overrides that default. When the command neither specifies nor reuses a particular parameter, the libpq default is used. Specifying any of `dbname`, `username`, `host` or `port` as `-` is equivalent to omitting that parameter.

If the new connection is successfully made, the previous connection is closed. If the connection attempt failed (wrong user name, access denied, etc.), the previous connection will only be kept if psql is in interactive mode. When executing a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos on the one hand, and a safety mechanism that scripts are not accidentally acting on the wrong database on the other hand.

Examples:

```
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c postgresql://tom@localhost/mydb?application_name=myapp
```

`\C` [ `title` ]

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to `\pset title title`. (The name of this command derives from "caption", as it was previously only used to set the caption in an HTML table.)

```
\cd [ directory ]
```

Changes the current working directory to *directory*. Without argument, changes to the current user's home directory.

### Tip

To print your current working directory, use `\! pwd`.

```
\conninfo
```

Outputs information about the current database connection.

```
\copy { table [ ( column_list ) ] | ( query ) } { from | to } { 'filename' | program
'command' | stdin | stdout | pstdin | pstdout } [ [ with ] ( option [, ...] ) ]
```

Performs a frontend (client) copy. This is an operation that runs an SQL COPY command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When *program* is specified, *command* is executed by psql and the data passed from or to *command* is routed between the server and the client. Again, the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

For `\copy ... from stdin`, data rows are read from the same source that issued the command, continuing until `\.` is read or the stream reaches EOF. This option is useful for populating tables in-line within a SQL script file. For `\copy ... to stdout`, output is sent to the same place as psql command output, and the COPY *count* command status is not printed (since it might be confused with a data row). To read/write psql's standard input or output regardless of the current command source or `\o` option, write *from pstdin* or *to pstdout*.

The syntax of this command is similar to that of the SQL COPY command. All options other than the data source/destination are as specified for COPY. Because of this, special parsing rules apply to the `\copy` meta-command. Unlike most other meta-commands, the entire remainder of the line is always taken to be the arguments of `\copy`, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Tip

This operation is not as efficient as the SQL COPY command because all data must pass through the client/server connection. For large amounts of data the SQL command might be preferable.

```
\copyright
```

Shows the copyright and distribution terms of .

```
\crosstabview [ colV [ colH [ colD [ sortcolH ] ] ] ]
```

Executes the current query buffer (like `\g`) and shows the results in a crosstab grid. The query must return at least three columns. The output column identified by *colV* becomes a vertical header and the output column identified by *colH* becomes a horizontal header. *colD* identifies the output column to display within the grid. *sortcolH* identifies an optional sort column for the horizontal header.

Each column specification can be a column number (starting at 1) or a column name. The usual SQL case folding and quoting rules apply to column names. If omitted, *colV* is taken as column 1 and *colH* as column 2. *colH* must differ from *colV*. If *colD* is not specified, then there must be exactly three columns in the query result, and the column that is neither *colV* nor *colH* is taken to be *colD*.

The vertical header, displayed as the leftmost column, contains the values found in column *colV*, in the same order as in the query results, but with duplicates removed.

The horizontal header, displayed as the first row, contains the values found in column *colH*, with duplicates removed. By default, these appear in the same order as in the query results. But if the optional *sortcolH* argument is given, it identifies a column whose values must be integer numbers, and the values from *colH* will appear in the horizontal header sorted according to the corresponding *sortcolH* values.

Inside the crosstab grid, for each distinct value *x* of *colH* and each distinct value *y* of *colV*, the cell located at the intersection (*x*, *y*) contains the value of the *colD* column in the query result row for which the value of *colH* is *x* and the value of *colV* is *y*. If there is no such row, the cell is empty. If there are multiple such rows, an error is reported.

`\d[S+] [ pattern ]`

For each relation (table, view, materialized view, index, sequence, or foreign table) or composite type matching the *pattern*, show all columns, their types, the tablespace (if not the default) and any special attributes such as NOT NULL or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well. (“Matching the pattern” is defined in the section called “Patterns” below.)

For some types of relation, `\d` shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.

The command form `\d+` is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view, a non-default replica identity setting.

By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

### Note

If `\d` is used without a *pattern* argument, it is equivalent to `\dtvmsE` which will show a list of all visible tables, views, materialized views, sequences and foreign tables. This is purely a convenience measure.

`\da[S] [ pattern ]`

Lists aggregate functions, together with their return type and the data types they operate on. If *pattern* is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

`\dA[+] [ pattern ]`

Lists access methods. If *pattern* is specified, only access methods whose names match the pattern are shown. If *+* is appended to the command name, each access method is listed with its associated handler function and description.

`\db[+] [ pattern ]`

Lists tablespaces. If *pattern* is specified, only tablespaces whose names match the pattern are shown. If *+* is appended to the command name, each tablespace is listed with its associated options, on-disk size, permissions and description.

`\dc[S+] [ pattern ]`

Lists conversions between character-set encodings. If *pattern* is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern

or the *s* modifier to include system objects. If + is appended to the command name, each object is listed with its associated description.

`\dC[+] [ pattern ]`

Lists type casts. If *pattern* is specified, only casts whose source or target types match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

`\dd[S] [ pattern ]`

Shows the descriptions of objects of type `constraint`, `operator class`, `operator family`, `rule`, and `trigger`. All other comments may be viewed by the respective backslash commands for those object types.

`\dd` displays descriptions for objects matching the *pattern*, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

Descriptions for objects can be created with the COMMENT SQL command.

`\dD[S+] [ pattern ]`

Lists domains. If *pattern* is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If + is appended to the command name, each object is listed with its associated permissions and description.

`\ddp [ pattern ]`

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If *pattern* is specified, only entries whose role name or schema name matches the pattern are listed.

The ALTER DEFAULT PRIVILEGES command is used to set default access privileges. The meaning of the privilege display is explained under GRANT.

`\dE[S+] [ pattern ]`

`\di[S+] [ pattern ]`

`\dm[S+] [ pattern ]`

`\ds[S+] [ pattern ]`

`\dt[S+] [ pattern ]`

`\dv[S+] [ pattern ]`

In this group of commands, the letters *E*, *i*, *m*, *s*, *t*, and *v* stand for foreign table, index, materialized view, sequence, table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, `\dit` lists indexes and tables. If + is appended to the command name, each object is listed with its physical size on disk and its associated description, if any. If *pattern* is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects.

`\des[+] [ pattern ]`

Lists foreign servers (mnemonic: “external servers”). If *pattern* is specified, only those servers whose name matches the pattern are listed. If the form `\des+` is used, a full description of each server is shown, including the server's ACL, type, version, options, and description.

`\det[+] [ pattern ]`

Lists foreign tables (mnemonic: “external tables”). If *pattern* is specified, only entries whose table name or schema name matches the pattern are listed. If the form `\det+` is used, generic options and the foreign table description are also displayed.

`\deu[+] [ pattern ]`

Lists user mappings (mnemonic: “external users”). If *pattern* is specified, only those mappings whose user names match the pattern are listed. If the form `\deu+` is used, additional information about each mapping is shown.

### Caution

`\deu+` might also display the user name and password of the remote user, so care should be taken not to disclose them.

`\dew[+] [ pattern ]`

Lists foreign-data wrappers (mnemonic: “external wrappers”). If *pattern* is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form `\dew+` is used, the ACL, options, and description of the foreign-data wrapper are also shown.

`\df[antwS+] [ pattern ]`

Lists functions, together with their result data types, argument data types, and function types, which are classified as “agg” (aggregate), “normal”, “trigger”, or “window”. To display only functions of specific type(s), add the corresponding letters *a*, *n*, *t*, or *w* to the command. If *pattern* is specified, only functions whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If the form `\df+` is used, additional information about each function is shown, including volatility, parallel safety, owner, security classification, access privileges, language, source code and description.

### Tip

To look up functions taking arguments or returning values of a specific data type, use your pager's search capability to scroll through the `\df` output.

`\dF[+] [ pattern ]`

Lists text search configurations. If *pattern* is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

`\dFd[+] [ pattern ]`

Lists text search dictionaries. If *pattern* is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

`\dFp[+] [ pattern ]`

Lists text search parsers. If *pattern* is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

`\dFt[+] [ pattern ]`

Lists text search templates. If *pattern* is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

`\dg[S+] [ pattern ]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\du`.) By default, only user-created roles are shown; supply the *s* modifier to include system roles. If *pattern* is specified, only those roles whose names match the

pattern are listed. If the form `\dg+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dl`

This is an alias for `\lo_list`, which shows a list of large objects.

`\dL[S+] [ pattern ]`

Lists procedural languages. If *pattern* is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the *s* modifier to include system objects. If *+* is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

`\dn[S+] [ pattern ]`

Lists schemas (namespaces). If *pattern* is specified, only schemas whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If *+* is appended to the command name, each object is listed with its associated permissions and description, if any.

`\do[S+] [ pattern ]`

Lists operators with their operand and result types. If *pattern* is specified, only operators whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If *+* is appended to the command name, additional information about each operator is shown, currently just the name of the underlying function.

`\dO[S+] [ pattern ]`

Lists collations. If *pattern* is specified, only collations whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the *s* modifier to include system objects. If *+* is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

`\dp [ pattern ]`

Lists tables, views and sequences with their associated access privileges. If *pattern* is specified, only tables, views and sequences whose names match the pattern are listed.

The GRANT and REVOKE commands are used to set access privileges. The meaning of the privilege display is explained under GRANT.

`\drds [ role-pattern [ database-pattern ] ]`

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. *role-pattern* and *database-pattern* are used to select specific roles and databases to list, respectively. If omitted, or if *\** is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The ALTER ROLE and ALTER DATABASE commands are used to define per-role and per-database configuration settings.

`\dRp[+] [ pattern ]`

Lists replication publications. If *pattern* is specified, only those publications whose names match the pattern are listed. If *+* is appended to the command name, the tables associated with each publication are shown as well.

`\dRs[+] [ pattern ]`

Lists replication subscriptions. If *pattern* is specified, only those subscriptions whose names match the pattern are listed. If *+* is appended to the command name, additional properties of the subscriptions are shown.

`\dT[S+] [ pattern ]`

Lists data types. If *pattern* is specified, only types whose names match the pattern are listed. If + is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an `enum` type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

`\du[S+] [ pattern ]`

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to `\dg`.) By default, only user-created roles are shown; supply the `s` modifier to include system roles. If *pattern* is specified, only those roles whose names match the pattern are listed. If the form `\du+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dx[+] [ pattern ]`

Lists installed extensions. If *pattern* is specified, only those extensions whose names match the pattern are listed. If the form `\dx+` is used, all the objects belonging to each matching extension are listed.

`\dy[+] [ pattern ]`

Lists event triggers. If *pattern* is specified, only those event triggers whose names match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

`\e` or `\edit [ filename ] [ line_number ]`

If *filename* is specified, the file is edited; after the editor exits, the file's content is copied into the current query buffer. If no *filename* is given, the current query buffer is copied to a temporary file which is then edited in the same fashion. Or, if the current query buffer is empty, the most recently executed query is copied to a temporary file and edited in the same fashion.

The new contents of the query buffer are then re-parsed according to the normal rules of psql, treating the whole buffer as a single line. Any complete queries are immediately executed; that is, if the query buffer contains or ends with a semicolon, everything up to that point is executed. Whatever remains will wait in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel it by clearing the query buffer. Treating the buffer as a single line primarily affects meta-commands: whatever is in the buffer after a meta-command will be taken as argument(s) to the meta-command, even if it spans multiple lines. (Thus you cannot make meta-command-using scripts this way. Use `\i` for that.)

If a line number is specified, psql will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, psql assumes it is a line number, not a file name.

### Tip

See under the section called “Environment” for how to configure and customize your editor.

`\echo text [ ... ]`

Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

```
=> \echo `date`
Tue Oct 26 21:40:57 CEST 1999
```

If the first argument is an unquoted `-n` the trailing newline is not written.

**Tip**

If you use the `\o` command to redirect your query output you might wish to use `\qecho` instead of this command.

`\ef [ function_description [ line_number ] ]`

This command fetches and edits the definition of the named function, in the form of a `CREATE` OR `REPLACE FUNCTION` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command waits in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If no function is specified, a blank `CREATE FUNCTION` template is presented for editing.

If a line number is specified, `psql` will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ef`, and neither variable interpolation nor backquote expansion are performed in the arguments.

**Tip**

See under the section called “Environment” for how to configure and customize your editor.

`\encoding [ encoding ]`

Sets the client character set encoding. Without an argument, this command shows the current encoding.

`\errverbose`

Repeats the most recent server error message at maximum verbosity, as though `VERBOSITY` were set to `verbose` and `SHOW_CONTEXT` were set to `always`.

`\ev [ view_name [ line_number ] ]`

This command fetches and edits the definition of the named view, in the form of a `CREATE` OR `REPLACE VIEW` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command waits in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

If no view is specified, a blank `CREATE VIEW` template is presented for editing.

If a line number is specified, `psql` will position the cursor on the specified line of the view definition.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\ev`, and neither variable interpolation nor backquote expansion are performed in the arguments.

`\f [ string ]`

Sets the field separator for unaligned query output. The default is the vertical bar (`|`). It is equivalent to `\pset fieldsep`.

`\g [ filename ]`

`\g [ |command ]`

Sends the current query buffer to the server for execution. If an argument is given, the query's output is written to the named file or piped to the given shell command, instead of displaying it as usual.

The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

If the current query buffer is empty, the most recently sent query is re-executed instead. Except for that behavior, `\g` without an argument is essentially equivalent to a semicolon. A `\g` with argument is a “one-shot” alternative to the `\o` command.

If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

#### `\gexec`

Sends the current query buffer to the server, then treats each column of each row of the query's output (if any) as a SQL statement to be executed. For example, to create an index on each column of `my_table`:

```
=> SELECT format('create index on my_table(%I)', attname)
-> FROM pg_attribute
-> WHERE attrelid = 'my_table'::regclass AND attnum > 0
-> ORDER BY attnum
-> \gexec
CREATE INDEX
CREATE INDEX
CREATE INDEX
CREATE INDEX
```

The generated queries are executed in the order in which the rows are returned, and left-to-right within each row if there is more than one column. NULL fields are ignored. The generated queries are sent literally to the server for processing, so they cannot be psql meta-commands nor contain psql variable references. If any individual query fails, execution of the remaining queries continues unless `ON_ERROR_STOP` is set. Execution of each query is subject to `ECHO` processing. (Setting `ECHO` to `all` or `queries` is often advisable when using `\gexec`.) Query logging, single-step mode, timing, and other query execution features apply to each generated query as well.

If the current query buffer is empty, the most recently sent query is re-executed instead.

#### `\gset [ prefix ]`

Sends the current query buffer to the server and stores the query's output into psql variables (see the section called “Variables”). The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a *prefix*, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

If the current query buffer is empty, the most recently sent query is re-executed instead.

```
\gx [ filename ]
\x [ |command ]
```

`\gx` is equivalent to `\g`, but forces expanded output mode for this query. See `\x`.

```
\h or \help [ command ]
```

Gives syntax help on the specified SQL command. If *command* is not specified, then psql will list all the commands for which syntax help is available. If *command* is an asterisk (\*), then syntax help on all SQL commands is shown.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\help`, and neither variable interpolation nor backquote expansion are performed in the arguments.

### Note

To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type `\help alter table`.

```
\H or \html
```

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

```
\i or \include filename
```

Reads input from the file *filename* and executes it as though it had been typed on the keyboard.

If *filename* is - (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

### Note

If you want to see the lines on the screen as they are read you must set the variable `ECHO` to `all`.

```
\if expression
\elif expression
\else
\endif
```

This group of commands implements nestable conditional blocks. A conditional block must begin with an `\if` and end with an `\endif`. In between there may be any number of `\elif` clauses, which may optionally be followed by a single `\else` clause. Ordinary queries and other types of backslash commands may (and usually do) appear between the commands forming a conditional block.

The `\if` and `\elif` commands read their argument(s) and evaluate them as a boolean expression. If the expression yields `true` then processing continues normally; otherwise, lines are skipped until a matching `\elif`, `\else`, or `\endif` is reached. Once an `\if` or `\elif` test has succeeded, the arguments of later `\elif` commands in the same block are not evaluated but are treated as false. Lines following an `\else` are processed only if no earlier matching `\if` or `\elif` succeeded.

The *expression* argument of an `\if` or `\elif` command is subject to variable interpolation and backquote expansion, just like any other backslash command argument. After that it is evaluated like the value of an on/off option variable. So a valid value is any unambiguous case-insensitive match for one of: `true`, `false`, `1`, `0`, `on`, `off`, `yes`, `no`. For example, `t`, `T`, and `tR` will all be considered to be `true`.

Expressions that do not properly evaluate to true or false will generate a warning and be treated as false.

Lines being skipped are parsed normally to identify queries and backslash commands, but queries are not sent to the server, and backslash commands other than conditionals (`\if`, `\elif`, `\else`, `\endif`) are ignored. Conditional commands are checked only for valid nesting. Variable references in skipped lines are not expanded, and backquote expansion is not performed either.

All the backslash commands of a given conditional block must appear in the same source file. If EOF is reached on the main input file or an `\include`-ed file before all local `\if`-blocks have been closed, then `psql` will raise an error.

Here is an example:

```
-- check for the existence of two separate records in the database and store
-- the results in separate psql variables
SELECT
    EXISTS(SELECT 1 FROM customer WHERE customer_id = 123) as is_customer,
    EXISTS(SELECT 1 FROM employee WHERE employee_id = 456) as is_employee
\gset
\if :is_customer
    SELECT * FROM customer WHERE customer_id = 123;
\elif :is_employee
    \echo 'is not a customer but is an employee'
    SELECT * FROM employee WHERE employee_id = 456;
\else
    \if yes
        \echo 'not a customer or employee'
    \else
        \echo 'this will never print'
    \endif
\endif
\ir or \include_relative filename
```

The `\ir` command is similar to `\i`, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, `\ir` interprets file names relative to the directory in which the script is located, rather than the current working directory.

```
\l[+] or \list[+] [ pattern ]
```

List the databases in the server and show their names, owners, character set encodings, and access privileges. If *pattern* is specified, only databases whose names match the pattern are listed. If `+` is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

```
\lo_export oid filename
```

Reads the large object with OID *loid* from the database and writes it to *filename*. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system.

### Tip

Use `\lo_list` to find out the large object's OID.

```
\lo_import filename [ comment ]
```

Stores the file into a large object. Optionally, it associates the given comment with the object. Example:

```
foo=> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801, which can be used to access the newly-created large object in the future. For the sake of readability, it is recommended to always associate a human-readable comment with every object. Both OIDs and comments can be viewed with the `\lo_list` command.

Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

`\lo_list`

Shows a list of all large objects currently stored in the database, along with any comments provided for them.

`\lo_unlink loid`

Deletes the large object with OID *loid* from the database.

### Tip

Use `\lo_list` to find out the large object's OID.

`\o or \out [ filename ]`

`\o or \out [ |command ]`

Arranges to save future query results to the file *filename* or pipe future results to the shell command *command*. If no argument is specified, the query output is reset to the standard output.

If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.

“Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`); but not error messages.

### Tip

To intersperse text output in between query results, use `\qecho`.

`\p or \print`

Print the current query buffer to the standard output. If the current query buffer is empty, the most recently executed query is printed instead.

`\password [ username ]`

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE` command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

`\prompt [ text ] name`

Prompts the user to supply text, which is assigned to the variable *name*. An optional prompt string, *text*, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch was used, `\prompt` uses standard input and standard output.

```
\pset [ option [ value ] ]
```

This command sets options affecting the output of query result tables. *option* indicates which option is to be set. The semantics of *value* vary depending on the selected option. For some options, omitting *value* causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting *value* just results in the current setting being displayed.

`\pset` without any arguments displays the current status of all printing options.

Adjustable printing options are:

`border`

The *value* must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the `border=...` attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the same as `border = 2`. The `latex` and `latex-longtable` formats additionally allow a value of 3 to add dividing lines between data rows.

`columns`

Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. Zero (the default) causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the `wrapped` format only affects screen output. If `columns` is nonzero then file and pipe output is wrapped to that width as well.

`expanded (or x)`

If *value* is specified it must be either `on` or `off`, which will enable or disable expanded mode, or `auto`. If *value* is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode. In the auto setting, the expanded mode is used whenever the query output has more than one column and is wider than the screen; otherwise, the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.

`fieldsep`

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

`fieldsep_zero`

Sets the field separator to use in unaligned output format to a zero byte.

`footer`

If *value* is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If *value* is omitted the command toggles footer display on or off.

`format`

Sets the output format to one of `unaligned`, `aligned`, `wrapped`, `html`, `asciidoc`, `latex` (uses `tabular`), `latex-longtable`, or `troff-ms`. Unique abbreviations are allowed. (That would mean one letter is enough.)

`unaligned` format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs (for example, tab-separated or comma-separated format).

`aligned` format is the standard, human-readable, nicely formatted text output; this is the default.

`wrapped` format is like `aligned` but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` will not attempt to wrap column header titles; therefore, `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

The `html`, `asciidoc`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. `latex-longtable` also requires the LaTeX `longtable` and `booktabs` packages.

#### `linestyle`

Sets the border line drawing style to one of `ascii`, `old-ascii`, or `unicode`. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

`ascii` style uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the `wrapped` format wraps data from one line to the next without a newline character, a dot (`.`) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

`old-ascii` style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in place of the left-hand column separator.

`unicode` style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, the `linestyle` option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

#### `null`

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer `\pset null '(null)'`.

#### `numericlocale`

If `value` is specified it must be either `on` or `off` which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If `value` is omitted the command toggles between regular and locale-specific numeric output.

#### `pager`

Controls use of a pager program for query and `psql` help output. If the environment variable `PAGER` is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as `more`) is used.

When the `pager` option is `off`, the pager program is not used. When the `pager` option is `on`, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The `pager` option can also be set to `always`, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. `\pset pager` without a `value` toggles pager use on and off.

`pager_min_lines`

If `pager_min_lines` is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

`recordsep`

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

`recordsep_zero`

Sets the record separator to use in unaligned output format to a zero byte.

`tableattr (or T)`

In HTML format, this specifies attributes to be placed inside the `table` tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don't want to specify `border` here, as that is already taken care of by `\pset border`. If no *value* is given, the table attributes are unset.

In `latex-longtable` format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g. `'0.2 0.2 0.6'`. Unspecified output columns use the last specified value.

`title (or C)`

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no *value* is given, the title is unset.

`tuples_only (or t)`

If *value* is specified it must be either `on` or `off` which will enable or disable tuples-only mode. If *value* is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.

`unicode_border_linestyle`

Sets the border drawing style for the `unicode` line style to one of `single` or `double`.

`unicode_column_linestyle`

Sets the column drawing style for the `unicode` line style to one of `single` or `double`.

`unicode_header_linestyle`

Sets the header drawing style for the `unicode` line style to one of `single` or `double`.

Illustrations of how these different formats look can be seen in the the section called “Examples” section.

### Tip

There are various shortcut commands for `\pset`. See `\a`, `\C`, `\f`, `\H`, `\t`, `\T`, and `\x`.

`\q` or `\quit`

Quits the psql program. In a script file, only execution of that script is terminated.

`\qecho text [ ... ]`

This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

`\r` or `\reset`

Resets (clears) the query buffer.

`\s` [ *filename* ]

Print psql's command line history to *filename*. If *filename* is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if psql was built without Readline support.

`\set` [ *name* [ *value* [ ... ] ] ]

Sets the psql variable *name* to *value*, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set to an empty-string value. To unset a variable, use the `\unset` command.

`\set` without any arguments displays the names and values of all currently-set psql variables.

Valid variable names can contain letters, digits, and underscores. See the section the section called "Variables" below for details. Variable names are case-sensitive.

Certain variables are special, in that they control psql's behavior or are automatically set to reflect connection state. These variables are documented in the section called "Variables", below.

### Note

This command is unrelated to the SQL command SET.

`\setenv` *name* [ *value* ]

Sets the environment variable *name* to *value*, or if the *value* is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

`\sf`[+] *function\_description*

This command fetches and shows the definition of the named function, in the form of a CREATE OR REPLACE FUNCTION command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sf`, and neither variable interpolation nor backquote expansion are performed in the arguments.

`\sv`[+] *view\_name*

This command fetches and shows the definition of the named view, in the form of a CREATE OR REPLACE VIEW command. The definition is printed to the current query output channel, as set by `\o`.

If `+` is appended to the command name, then the output lines are numbered from 1.

Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\sv`, and neither variable interpolation nor backquote expansion are performed in the arguments.

- 
- `\t`
- Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.
- `\T table_options`
- Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`.
- `\timing [ on | off ]`
- With a parameter, turns displaying of how long each SQL statement takes on or off. Without a parameter, toggles the display between on and off. The display is in milliseconds; intervals longer than 1 second are also shown in minutes:seconds format, with hours and days fields added if needed.
- `\unset name`
- Unsets (deletes) the psql variable *name*.
- Most variables that control psql's behavior cannot be unset; instead, an `\unset` command is interpreted as setting them to their default values. See the section called “Variables”, below.
- `\w` or `\write filename`  
`\w` or `\write |command`
- Writes the current query buffer to the file *filename* or pipes it to the shell command *command*. If the current query buffer is empty, the most recently executed query is written instead.
- If the argument begins with `|`, then the entire remainder of the line is taken to be the *command* to execute, and neither variable interpolation nor backquote expansion are performed in it. The rest of the line is simply passed literally to the shell.
- `\watch [ seconds ]`
- Repeatedly execute the current query buffer (as `\g` does) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions. Each query result is displayed with a header that includes the `\pset title` string (if any), the time as of query start, and the delay interval.
- If the current query buffer is empty, the most recently sent query is re-executed instead.
- `\x [ on | off | auto ]`
- Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.
- `\z [ pattern ]`
- Lists tables, views and sequences with their associated access privileges. If a *pattern* is specified, only tables, views and sequences whose names match the pattern are listed.
- This is an alias for `\dp` (“display privileges”).
- `\! [ command ]`
- With no argument, escapes to a sub-shell; psql resumes when the sub-shell exits. With an argument, executes the shell command *command*.
- Unlike most other meta-commands, the entire remainder of the line is always taken to be the argument(s) of `\!`, and neither variable interpolation nor backquote expansion are performed in the arguments. The rest of the line is simply passed literally to the shell.
- `\? [ topic ]`
- Shows help information. The optional *topic* parameter (defaulting to `commands`) selects which part of psql is explained: `commands` describes psql's backslash commands; `options` describes the com-

mand-line options that can be passed to psql; and `variables` shows help about psql configuration variables.

## Patterns

The various `\d` commands accept a *pattern* parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO" "BAR"` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Whenever the *pattern* parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using `*` as the pattern. (An object is said to be *visible* if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use `*.*` as the pattern.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.*bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in Section 9.7.3, except for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.*`, `?` which is translated to `.`, and `$` which is matched literally. You can emulate these pattern characters at need by writing `? for .`, `(R+|)` for `R*`, or `(R|)` for `R?`. `$` is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, `$` is automatically appended to your pattern). Write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of `\do`).

## Advanced Features

### Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command `\set`. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in the section called “SQL Interpolation”, below.

If you call `\set` without a second argument, the variable is set to an empty-string value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

### Note

The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

Variables that control psql's behavior generally cannot be unset or set to invalid values. An `\unset` command is allowed but is interpreted as setting the variable to its default value. A `\set` command without a second argument is interpreted as setting the variable to `on`, for control variables that accept that value, and is rejected for others. Also, control variables that accept the values `on` and `off` will also accept other common spellings of Boolean values, such as `true` and `false`.

The specially treated variables are:

#### AUTOCOMMIT

When `on` (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION` SQL command. When `off` or `unset`, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-off mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

### Note

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

### Note

The autocommit-on mode is 's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psql-rc` file or your `~/.psqlrc` file.

#### COMP\_KEYWORD\_CASE

Determines which letter case to use when completing an SQL key word. If set to `lower` or `upper`, the completed word will be in lower or upper case, respectively. If set to `preserve-lower` or `preserve-upper` (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

## DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

## ECHO

If set to `all`, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch `-a`. If set to `queries`, psql prints each query to standard output as it is sent to the server. The switch to select this behavior is `-e`. If set to `errors`, then only failed queries are displayed on standard error output. The switch for this behavior is `-b`. If set to `none` (the default), then no queries are displayed.

## ECHO\_HIDDEN

When this variable is set to `on` and a backslash command queries the database, the query is first shown. This feature helps you to study internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.) If you set this variable to the value `noexec`, the queries are just shown but are not actually sent to the server and executed. The default value is `off`.

## ENCODING

The current client character set encoding. This is set every time you connect to a database (including program start-up), and when you change the encoding with `\encoding`, but it can be changed or unset.

## FETCH\_COUNT

If this variable is set to an integer value greater than zero, the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

**Tip**

Although you can use any output format with this feature, the default `aligned` format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

## HISTCONTROL

If this variable is set to `ignorespace`, lines which begin with a space are not entered into the history list. If set to a value of `ignoredups`, lines matching the previous history line are not entered. A value of `ignoreboth` combines the two options. If set to `none` (the default), all lines read in interactive mode are saved on the history list.

**Note**

This feature was shamelessly plagiarized from Bash.

## HISTFILE

The file name that will be used to store the history list. If unset, the file name is taken from the `PSQL_HISTORY` environment variable. If that is not set either, the default is `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows. For example, putting:

```
\set HISTFILE ~/.psql_history- :DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

**Note**

This feature was shamelessly plagiarized from Bash.

## HISTSIZE

The maximum number of commands to store in the command history (default 500). If set to a negative value, no limit is applied.

**Note**

This feature was shamelessly plagiarized from Bash.

## HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be changed or unset.

## IGNOREEOF

If set to 1 or less, sending an EOF character (usually **Control+D**) to an interactive session of `psql` will terminate the application. If set to a larger numeric value, that many consecutive EOF characters must be typed to make an interactive session terminate. If the variable is set to a non-numeric value, it is interpreted as 10. The default is 0.

**Note**

This feature was shamelessly plagiarized from Bash.

## LASTOID

The value of the last affected OID, as returned from an `INSERT` or `\lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

## ON\_ERROR\_ROLLBACK

When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When set to `off` (the default), a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

## ON\_ERROR\_STOP

By default, command processing continues after an error. When this variable is set to `on`, processing will instead stop immediately. In interactive mode, `psql` will return to the command prompt; otherwise, `psql` will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

## PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be changed or unset.

PROMPT1  
PROMPT2  
PROMPT3

These specify what the prompts psql issues should look like. See the section called “Prompting” below.

QUIET

Setting this variable to `on` is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

SERVER\_VERSION\_NAME  
SERVER\_VERSION\_NUM

The server's version number as a string, for example `9.6.2`, `10.1` or `11beta1`, and in numeric form, for example `90602` or `100001`. These are set every time you connect to a database (including program start-up), but can be changed or unset.

SHOW\_CONTEXT

This variable can be set to the values `never`, `errors`, or `always` to control whether `CONTEXT` fields are displayed in messages from the server. The default is `errors` (meaning that context will be shown in error messages, but not in notice or warning messages). This setting has no effect when `VERBOSITY` is set to `terse`. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

SINGLELINE

Setting this variable to `on` is equivalent to the command line option `-s`.

SINGLESTEP

Setting this variable to `on` is equivalent to the command line option `-s`.

USER

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be changed or unset.

VERBOSITY

This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports. (See also `\errverbose`, for use when you want a verbose version of the error you just got.)

VERSION  
VERSION\_NAME  
VERSION\_NUM

These variables are set at program start-up to reflect psql's version, respectively as a verbose string, a short string (e.g., `9.6.2`, `10.1`, or `11beta1`), and a number (e.g., `90602` or `100001`). They can be changed or unset.

## SQL Interpolation

A key feature of psql variables is that you can substitute (“interpolate”) them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (`:`). For example,

```
testdb=> \set foo 'my_table'  
testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `':foo'` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
testdb=> \set content `cat my_file.txt`
testdb=> INSERT INTO my_table VALUES (:content');
```

(Note that this still won't work if `my_file.txt` contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `:"name"`) is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a psql extension.

## Prompting

The prompts psql issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

`%M`  
The full host name (with domain name) of the database server, or `[local]` if the connection is over a Unix domain socket, or `[local:/dir/name]`, if the Unix domain socket is not at the compiled in default location.

`%m`  
The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a Unix domain socket.

`%>`  
The port number at which the database server is listening.

`%n`  
The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

- 
- `%/`  
The name of the current database.
- `%~`  
Like `%/`, but the output is `~` (tilde) if the database is your default database.
- `%#`  
If the session user is a database superuser, then a `#`, otherwise a `>`. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)
- `%p`  
The process ID of the backend currently connected to.
- `%R`  
In prompt 1 normally `=`, but `@` if the session is in an inactive branch of a conditional block, or `^` if in single-line mode, or `!` if the session is disconnected from the database (which can happen if `\connect` fails). In prompt 2 `%R` is replaced by a character that depends on why psql expects more input: `-` if the command simply wasn't terminated yet, but `*` if there is an unfinished `/* ... */` comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or `(` if there is an unmatched left parenthesis. In prompt 3 `%R` doesn't produce anything.
- `%x`  
Transaction status: an empty string when not in a transaction block, or `*` when in a transaction block, or `!` when in a failed transaction block, or `?` when the transaction state is indeterminate (for example, because there is no connection).
- `%l`  
The line number inside the current statement, starting from 1.
- `%digits`  
The character with the indicated octal code is substituted.
- `%:name:`  
The value of the psql variable `name`. See the section the section called “Variables” for details.
- `%`command``  
The output of `command`, similar to ordinary “back-tick” substitution.
- `%[ ... %]`  
Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `%)`. Multiple pairs of these can occur within the prompt. For example:  

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]n@%/%R%[%033[0m%]## '
```

  
results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.
- To insert a percent sign into your prompt, write `%%`. The default prompts are `'%/%R%# '` for prompts 1 and 2, and `'>> '` for prompt 3.
-

## Note

This feature was shamelessly plagiarized from tcsh.

## Command-Line Editing

psql supports the Readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g. `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

## Environment

### COLUMNS

If `\pset columns` is zero, controls the width for the `wrapped` format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

### PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. Use of the pager can be disabled by setting `PAGER` to empty, or by using pager-related options of the `\pset` command.

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters (see Section 34.14).

PSQL\_EDITOR  
EDITOR  
VISUAL

Editor used by the `\e`, `\ef`, and `\ev` commands. These variables are examined in the order listed; the first that is set is used.

The built-in default editors are `vi` on Unix systems and `notepad.exe` on Windows systems.

### PSQL\_EDITOR\_LINENUMBER\_ARG

When `\e`, `\ef`, or `\ev` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

**PSQL\_HISTORY**

Alternative location for the command history file. Tilde (~) expansion is performed.

**PSQLRC**

Alternative location of the user's `.psqlrc` file. Tilde (~) expansion is performed.

**SHELL**

Command executed by the `\!` command.

**TMPDIR**

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Files

**psqlrc and ~/.psqlrc**

Unless it is passed an `-x` option, `psql` attempts to read and execute commands from the system-wide startup file (`psqlrc`) and then the user's personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc` and is sought in the installation's "system configuration" directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be `./etc/` relative to the directory containing the executables. The name of this directory can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user's personal startup file is named `.psqlrc` and is sought in the invoking user's home directory. On Windows, which lacks such a concept, the personal startup file is named `%APPDATA%\postgresql\psqlrc.conf`. The location of the user's startup file can be set explicitly via the `PSQLRC` environment variable.

Both the system-wide startup file and the user's personal startup file can be made `psql`-version-specific by appending a dash and the major or minor release number to the file name, for example `~/.psqlrc-9.2` or `~/.psqlrc-9.2.5`. The most specific version-matching file will be read in preference to a non-version-specific file.

**.psql\_history**

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the `HISTFILE` `psql` variable or the `PSQL_HISTORY` environment variable.

## Notes

- `psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with servers of versions back to 7.4, though not necessarily with servers newer than `psql` itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use `psql` to connect to several servers of different major versions, it is recommended that you use the newest version of `psql`. Alternatively, you can keep around a copy of `psql` from

each major version and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

- Before 9.6, the `-c` option implied `-X` (`--no-psqlrc`); this is no longer the case.
- Before PostgreSQL 8.4, `psql` allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. Now, some whitespace is required.

## Notes for Windows Users

`psql` is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within `psql`. If `psql` detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to `Lucida Console`, because the raster font does not work with the ANSI code page.

By default, `psql` works in the UTF-8 encoding and uses Windows Unicode API for console output. The console code page must be set to 65001 to ensure the correct display of all characters supported by your Windows console font.

Windows installer ships the `less.exe` pager with UTF-8 support and provides a shortcut that opens the console window with `Lucida Console` font and codepage 65001 settings. If you use a different pager, make sure it also supports UTF-8.

You can override the default `psql` encoding by setting the `PGCLIENTENCODING` environment variable.

## Examples

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (
testdb(>   first integer not null default 0,
testdb(>   second text)
testdb-> ;
CREATE TABLE
```

Now look at the table definition again:

```
testdb=> \d my_table
          Table "public.my_table"
  Column | Type      | Collation | Nullable | Default
-----+-----+-----+-----+-----
  first  | integer  |           | not null | 0
  second | text     |           |         |
```

Now we change the prompt to something more interesting:

```
testdb=> \set PROMPT1 '%n@m %~%R%# '
peter@localhost testdb=>
```

Let's assume you have filled the table with data and want to take a look at it:

```
peter@localhost testdb=> SELECT * FROM my_table;
  first | second
-----+-----
    1  | one
```

```

2 | two
3 | three
4 | four
(4 rows)

```

You can display tables in different ways by using the `\pset` command:

```

peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;
+-----+-----+
| first | second |
+-----+-----+
|     1 | one    |
|     2 | two    |
|     3 | three  |
|     4 | four   |
+-----+-----+
(4 rows)

```

```

peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;
first second
-----
1 one
2 two
3 three
4 four
(4 rows)

```

```

peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep ", "
Field separator is ", ".
peter@localhost testdb=> \pset tuples_only
Showing only tuples.
peter@localhost testdb=> SELECT second, first FROM my_table;
one,1
two,2
three,3
four,4

```

Alternatively, use the short commands:

```

peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
-[ RECORD 1 ]-
first | 1
second | one
-[ RECORD 2 ]-
first | 2
second | two
-[ RECORD 3 ]-

```

```

first | 3
second | three
-[ RECORD 4 ]-
first | 4
second | four

```

When suitable, query results can be shown in a crosstab representation with the `\crosstabview` command:

```

testdb=> SELECT first, second, first > 2 AS gt2 FROM my_table;

```

```

first | second | gt2
-----+-----+-----
1 | one | f
2 | two | f
3 | three | t
4 | four | t
(4 rows)

```

```

testdb=> \crosstabview first second

```

```

first | one | two | three | four
-----+-----+-----+-----+-----
1 | f | | | |
2 | | f | | |
3 | | | t | |
4 | | | | t |
(4 rows)

```

This second example shows a multiplication table with rows sorted in reverse numerical order and columns with an independent, ascending numerical order.

```

testdb=> SELECT t1.first as "A", t2.first+100 AS "B", t1.first*(t2.first+100) as "AxB",
testdb(> row_number() over(order by t2.first) AS ord
testdb(> FROM my_table t1 CROSS JOIN my_table t2 ORDER BY 1 DESC
testdb(> \crosstabview "A" "B" "AxB" ord

```

```

A | 101 | 102 | 103 | 104
---+---+---+---+---
4 | 404 | 408 | 412 | 416
3 | 303 | 306 | 309 | 312
2 | 202 | 204 | 206 | 208
1 | 101 | 102 | 103 | 104
(4 rows)

```

---

# reindexdb

reindexdb — reindex a database

## Synopsis

```
reindexdb [connection-option...] [option...] [ --schema | -S schema ] ... [ --table | -t table ] ... [ --index | -i index ] ... [dbname]
```

```
reindexdb [connection-option...] [option...] --all | -a
```

```
reindexdb [connection-option...] [option...] --system | -s [dbname]
```

## Description

reindexdb is a utility for rebuilding indexes in a database.

reindexdb is a wrapper around the SQL command REINDEX. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

## Options

reindexdb accepts the following command-line arguments:

-a  
--all

Reindex all databases.

[-d] *dbname*  
[--dbname=] *dbname*

Specifies the name of the database to be reindexed. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e  
--echo

Echo the commands that reindexdb generates and sends to the server.

-i *index*  
--index=*index*

Recreate *index* only. Multiple indexes can be recreated by writing multiple -i switches.

-q  
--quiet

Do not display progress messages.

-s  
--system

Reindex database's system catalogs.

-S *schema*  
--schema=*schema*

Reindex *schema* only. Multiple schemas can be reindexed by writing multiple -S switches.

-t *table*  
--table=*table*

Reindex *table* only. Multiple tables can be reindexed by writing multiple -t switches.

`-v`  
`--verbose`

Print detailed information during processing.

`-V`  
`--version`

Print the reindexdb version and exit.

`-?`  
`--help`

Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to discover what other databases should be reindexed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Diagnostics

In case of difficulty, see REINDEX and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

reindexdb might need to connect several times to the server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See Section 34.15 for more information.

## Examples

To reindex the database `test`:

```
$ reindexdb test
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table=foo --index=bar abcd
```

REINDEX

---

# vacuumdb

vacuumdb — garbage-collect and analyze a database

## Synopsis

```
vacuumdb [connection-option...] [option...] [ --table | -t table [( column [,...] )] ] ... [dbname]
```

```
vacuumdb [connection-option...] [option...] --all | -a
```

## Description

vacuumdb is a utility for cleaning a database. vacuumdb will also generate internal statistics used by the query optimizer.

vacuumdb is a wrapper around the SQL command VACUUM. There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

## Options

vacuumdb accepts the following command-line arguments:

-a  
--all

Vacuum all databases.

[-d] *dbname*  
[--dbname=] *dbname*

Specifies the name of the database to be cleaned or analyzed. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e  
--echo

Echo the commands that vacuumdb generates and sends to the server.

-f  
--full

Perform “full” vacuuming.

-F  
--freeze

Aggressively “freeze” tuples.

-j *njobs*  
--jobs=*njobs*

Execute the vacuum or analyze commands in parallel by running *njobs* commands simultaneously. This option reduces the time of the processing but it also increases the load on the database server.

vacuumdb will open *njobs* connections to the database, so make sure your max\_connections setting is high enough to accommodate all connections.

Note that using this mode together with the -f (FULL) option might cause deadlock failures if certain system catalogs are processed in parallel.

-q  
--quiet

Do not display progress messages.

-t *table* [ (*column* [,...]) ]  
--table=*table* [ (*column* [,...]) ]

Clean or analyze *table* only. Column names can be specified only in conjunction with the `--analyze` or `--analyze-only` options. Multiple tables can be vacuumed by writing multiple `-t` switches.

### Tip

If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

-v  
--verbose

Print detailed information during processing.

-V  
--version

Print the vacuumdb version and exit.

-z  
--analyze

Also calculate statistics for use by the optimizer.

-Z  
--analyze-only

Only calculate statistics for use by the optimizer (no vacuum).

--analyze-in-stages

Only calculate statistics for use by the optimizer (no vacuum), like `--analyze-only`. Run several (currently three) stages of analyze with different configuration settings, to produce usable statistics faster.

This option is useful to analyze a database that was newly populated from a restored dump or by `pg_upgrade`. This option will try to create some statistics as fast as possible, to make the database usable, and then produce full statistics in the subsequent stages.

-?  
--help

Show help about vacuumdb command line arguments, and exit.

vacuumdb also accepts the following command-line arguments for connection parameters:

-h *host*  
--host=*host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p *port*  
--port=*port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force vacuumdb to prompt for a password before connecting to a database.

This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to discover what other databases should be vacuumed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

## Environment

`PGDATABASE`  
`PGHOST`  
`PGPORT`  
`PGUSER`

Default connection parameters

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Diagnostics

In case of difficulty, see `VACUUM` and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

`vacuumdb` might need to connect several times to the server, asking for a password each time. It is convenient to have a `~/ .pgpass` file in such cases. See Section 34.15 for more information.

## Examples

To clean the database `test`:

```
$ vacuumdb test
```

To clean and analyze for the optimizer a database named `bigdb`:

```
$ vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `xyzzzy`, and analyze a single column `bar` of the table for the optimizer:

```
$ vacuumdb --analyze --verbose --table='foo(bar)' xyzzzy
```

**See Also**  
VACUUM

---

# Server Applications

This part contains reference information for server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in Client Applications.

---

# initdb

initdb — create a new database cluster

## Synopsis

```
initdb [option...] [ --pgdata | -D ] directory
```

## Description

`initdb` creates a new database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the `template1` and `postgres` databases. When you later create a new database, everything in the `template1` database is copied. (Therefore, anything installed in `template1` is automatically copied into each database created later.) The `postgres` database is a default database meant for use by users, utilities and third party applications.

Although `initdb` will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use `chown` to assign ownership of that directory to the database user account, then `su` to become the database user to run `initdb`.

`initdb` must be run as the user that will own the server process, because the server needs to have access to the files and directories that `initdb` creates. Since the server cannot be run as root, you must not run `initdb` as root either. (It will in fact refuse to do so.)

`initdb` initializes the database cluster's default locale and character set encoding. The character set encoding, collation order (`LC_COLLATE`) and character set classes (`LC_CTYPE`, e.g. upper, lower, digit) can be set separately for a database when it is created. `initdb` determines those settings for the `template1` database, which will serve as the default for all other databases.

To alter the default collation order or character set classes, use the `--lc-collate` and `--lc-ctype` options. Collation orders other than `C` or `POSIX` also have a performance penalty. For these reasons it is important to choose the right locale when running `initdb`.

The remaining locale categories can be changed later when the server is started. You can also use `--locale` to set the default for all locale categories, including collation order and character set classes. All server locale values (`lc_*`) can be displayed via `SHOW ALL`. More details can be found in Section 24.1.

To alter the default encoding, use the `--encoding`. More details can be found in Section 24.3.

## Options

`-A authmethod`

`--auth=authmethod`

This option specifies the default authentication method for local users used in `pg_hba.conf` (host and local lines). `initdb` will prepopulate `pg_hba.conf` entries using the specified authentication method for non-replication as well as replication connections.

Do not use `trust` unless you trust all local users on your system. `trust` is the default for ease of installation.

`--auth-host=authmethod`

This option specifies the authentication method for local users via TCP/IP connections used in `pg_hba.conf` (host lines).

---

`--auth-local=authmethod`

This option specifies the authentication method for local users via Unix-domain socket connections used in `pg_hba.conf` (local lines).

`-D directory`  
`--pgdata=directory`

This option specifies the directory where the database cluster should be stored. This is the only information required by `initdb`, but you can avoid writing it by setting the `PGDATA` environment variable, which can be convenient since the database server (`postgres`) can find the database directory later by the same variable.

`-E encoding`  
`--encoding=encoding`

Selects the encoding of the template database. This will also be the default encoding of any database you create later, unless you override it there. The default is derived from the locale, or `SQL_ASCII` if that does not work. The character sets supported by the server are described in Section 24.3.1.

`-k`  
`--data-checksums`

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. This option can only be set during initialization, and cannot be changed later. If set, checksums are calculated for all objects, in all databases.

`--locale=locale[@provider]`

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that `initdb` runs in. Locale support is described in Section 24.1.

Optionally, you can specify the default collation provider after the `@` symbol. Supported values are `icu` and `libc`. For details, see Section 24.2.2.

`--lc-collate=locale[@provider]`  
`--lc-ctype=locale`  
`--lc-messages=locale`  
`--lc-monetary=locale`  
`--lc-numeric=locale`  
`--lc-time=locale`

Like `--locale`, but only sets the locale in the specified category.

`--no-locale`

Equivalent to `--locale=C`.

`-N`  
`--no-sync`

By default, `initdb` will wait for all files to be written safely to disk. This option causes `initdb` to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

`--pwfile=filename`

Makes `initdb` read the database superuser's password from a file. The first line of the file is taken as the password.

-S  
--sync-only  
Safely write all database files to disk and exit. This does not perform any of the normal initdb operations.

-T *config*  
--text-search-config=*config*  
Sets the default text search configuration. See `default_text_search_config` for further information.

-U *username*  
--username=*username*  
Selects the user name of the database superuser. This defaults to the name of the effective user running `initdb`. It is really not important what the superuser's name is, but one might choose to keep the customary name `postgres`, even if the operating system user's name is different.

-W  
--pwprompt  
Makes `initdb` prompt for a password to give the database superuser. If you don't plan on using password authentication, this is not important. Otherwise you won't be able to use password authentication until you have a password set up.

-X *directory*  
--waldir=*directory*  
This option specifies the directory where the write-ahead log should be stored.

Other, less commonly used, options are also available:

-d  
--debug  
Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program `initdb` uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

-L *directory*  
Specifies where `initdb` should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

-n  
--no-clean  
By default, when `initdb` determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

Other options:

-V  
--version  
Print the `initdb` version and exit.

-?  
--help  
Show help about `initdb` command line arguments, and exit.

## Environment

### PGDATA

Specifies the directory where the database cluster is to be stored; can be overridden using the `-D` option.

### TZ

Specifies the default time zone of the created database cluster. The value should be a full time zone name (see Section 8.5.3).

This utility, like most other utilities, also uses the environment variables supported by libpq (see Section 34.14).

## Notes

`initdb` can also be invoked via `pg_ctl initdb`.

## See Also

`pg_ctl`, `postgres`

---

# pg\_archivecleanup

pg\_archivecleanup — clean up WAL archive files

## Synopsis

```
pg_archivecleanup [option...] archivelocation oldestkeptwalfile
```

## Description

pg\_archivecleanup is designed to be used as an `archive_cleanup_command` to clean up WAL file archives when running as a standby server (see Section 27.2). pg\_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg\_archivecleanup, put this into its `recovery.conf` configuration file:

```
archive_cleanup_command = 'pg_archivecleanup archivelocation %r'
```

where *archivelocation* is the directory from which WAL segment files should be removed.

When used within `archive_cleanup_command`, all WAL files logically preceding the value of the `%r` argument will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the *oldestkeptwalfile* will be removed from *archivelocation*. In this mode, if you specify a `.partial` or `.backup` file name, then only the file prefix will be used as the *oldestkeptwalfile*. This treatment of `.backup` file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name `000000010000003700000010`:

```
pg_archivecleanup -d archive 000000010000003700000010.00000020.backup
```

```
pg_archivecleanup: keep WAL file "archive/000000010000003700000010" and later
pg_archivecleanup: removing file "archive/00000001000000370000000F"
pg_archivecleanup: removing file "archive/00000001000000370000000E"
```

pg\_archivecleanup assumes that *archivelocation* is a directory readable and writable by the server-owning user.

## Options

pg\_archivecleanup accepts the following command-line arguments:

`-d`

Print lots of debug logging output on `stderr`.

`-n`

Print the names of the files that would have been removed on `stdout` (performs a dry run).

`-V`

`--version`

Print the pg\_archivecleanup version and exit.

`-x extension`

Provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: `-x .gz`.

`-?`

`--help`

Show help about `pg_archivecleanup` command line arguments, and exit.

## Notes

`pg_archivecleanup` is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

`pg_archivecleanup` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

## Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory

---

# pg\_controldata

pg\_controldata — display control information of a database cluster

## Synopsis

```
pg_controldata [option] [[-D] datadir]
```

## Description

pg\_controldata prints information initialized during `initdb`, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable `PGDATA`. This utility supports the options `-v` and `--version`, which print the pg\_controldata version and exit. It also supports options `-?` and `--help`, which output the supported arguments.

## Environment

PGDATA

Default data directory location

---

## pg\_ctl

pg\_ctl — initialize, start, stop, or control a server

### Synopsis

```
pg_ctl init [db] [-D datadir] [-s] [-o initdb-options]
```

```
pg_ctl start [-D datadir] [-l filename] [-W] [-t seconds] [-s] [-o options] [-p path] [-c]
```

```
pg_ctl stop [-D datadir] [-m s[mart] | f[ast] | i[mmediate] ] [-W] [-t seconds] [-s]
```

```
pg_ctl restart [-D datadir] [-m s[mart] | f[ast] | i[mmediate] ] [-W] [-t seconds] [-s] [-o options] [-c]
```

```
pg_ctl reload [-D datadir] [-s]
```

```
pg_ctl status [-D datadir]
```

```
pg_ctl promote [-D datadir] [-W] [-t seconds] [-s]
```

```
pg_ctl kill signal_name process_id
```

On Microsoft Windows, also:

```
pg_ctl register [-D datadir] [-N servicename] [-U username] [-P password] [-S a[uto] | d[emand] ] [-e source] [-W] [-t seconds] [-s] [-o options]
```

```
pg_ctl unregister [-N servicename]
```

### Description

pg\_ctl is a utility for initializing a database cluster, starting, stopping, or restarting the database server (postgres), or displaying the status of a running server. Although the server can be started manually, pg\_ctl encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The `init` or `initdb` mode creates a new database cluster, that is, a collection of databases that will be managed by a single server instance. This mode invokes the `initdb` command. See `initdb` for details.

The `start` mode launches a new server. The server is started in the background, and its standard input is attached to `/dev/null` (or `nul` on Windows). On Unix-like systems, by default, the server's standard output and standard error are sent to pg\_ctl's standard output (not standard error). The standard output of pg\_ctl should then be redirected to a file or piped to another process such as a log rotating program like `rotatelogs`; otherwise `postgres` will write its output to the controlling terminal (from the background) and will not leave the shell's process group. On Windows, by default the server's standard output and standard error are sent to the terminal. These default behaviors can be changed by using `-l` to append the server's output to a log file. Use of either `-l` or output redirection is recommended.

The `stop` mode shuts down the server that is running in the specified data directory. Three different shutdown methods can be selected with the `-m` option. "Smart" mode waits for all active clients to disconnect and any online backup to finish. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. "Fast" mode (the default) does not wait for clients to disconnect and will terminate an online backup in progress. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. "Immediate" mode will abort all server processes immediately, without a clean shutdown. This choice will lead to a crash-recovery cycle during the next server start.

`restart` mode effectively executes a stop followed by a start. This allows changing the `postgres` command-line options, or changing configuration-file options that cannot be changed without restarting the server. If relative paths were used on the command line during server start, `restart` might fail unless `pg_ctl` is executed in the same current directory as it was during server start.

`reload` mode simply sends the `postgres` server process a SIGHUP signal, causing it to reread its configuration files (`postgresql.conf`, `pg_hba.conf`, etc.). This allows changing configuration-file options that do not require a full server restart to take effect.

`status` mode checks whether a server is running in the specified data directory. If it is, the server's PID and the command line options that were used to invoke it are displayed. If the server is not running, `pg_ctl` returns an exit status of 3. If an accessible data directory is not specified, `pg_ctl` returns an exit status of 4.

`promote` mode commands the standby server that is running in the specified data directory to end standby mode and begin read-write operations.

`kill` mode sends a signal to a specified process. This is primarily valuable on Microsoft Windows which does not have a built-in kill command. Use `--help` to see a list of supported signal names.

`register` mode registers the server as a system service on Microsoft Windows. The `-s` option allows selection of service start type, either "auto" (start service automatically on system startup) or "demand" (start service on demand).

`unregister` mode unregisters a system service on Microsoft Windows. This undoes the effects of the `register` command.

## Options

`-c`  
`--core-files`

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.

`-D datadir`  
`--pgdata=datadir`

Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-l filename`  
`--log=filename`

Append the server log output to `filename`. If the file does not exist, it is created. The umask is set to 077, so access to the log file is disallowed to other users by default.

`-m mode`  
`--mode=mode`

Specifies the shutdown mode. `mode` can be `smart`, `fast`, or `immediate`, or the first letter of one of these three. If this option is omitted, `fast` is the default.

`-o options`  
`--options=options`

Specifies options to be passed directly to the `postgres` command. `-o` can be specified multiple times, with all the given options being passed through.

The `options` should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

---

`-o initdb-options`  
`--options=initdb-options`

Specifies options to be passed directly to the `initdb` command. `-o` can be specified multiple times, with all the given options being passed through.

The *options* should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

`-p path`

Specifies the location of the `postgres` executable. By default the `postgres` executable is taken from the same directory as `pg_ctl`, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the `postgres` executable was not found.

In `init` mode, this option analogously specifies the location of the `initdb` executable.

`-s`  
`--silent`

Print only errors, no informational messages.

`-t seconds`  
`--timeout=seconds`

Specifies the maximum number of seconds to wait when waiting for an operation to complete (see option `-w`). Defaults to the value of the `PGCTLTIMEOUT` environment variable or, if not set, to 60 seconds.

`-V`  
`--version`

Print the `pg_ctl` version and exit.

`-w`  
`--wait`

Wait for the operation to complete. This is supported for the modes `start`, `stop`, `restart`, `promote`, and `register`, and is the default for those modes.

When waiting for startup, `pg_ctl` repeatedly attempts to connect to the server. When waiting for shutdown, `pg_ctl` waits for the server to remove its PID file. `pg_ctl` returns an exit code based on the success of the startup or shutdown.

If the operation does not complete within the timeout (see option `-t`), then `pg_ctl` exits with a nonzero exit status. But note that the operation might continue in the background and eventually succeed.

`-W`  
`--no-wait`

Do not wait for the operation to complete. This is the opposite of the option `-w`.

If waiting is disabled, the requested action is triggered, but there is no feedback about its success. In that case, the server log file or an external monitoring system would have to be used to check the progress and success of the operation.

In prior releases of `pg_ctl`, this was the default except for the `stop` mode.

`-?`  
`--help`

Show help about `pg_ctl` command line arguments, and exit.

If an option is specified that is valid, but not relevant to the selected operating mode, `pg_ctl` ignores it.

## Options for Windows

`-e source`

Name of the event source for `pg_ctl` to use for logging to the event log when running as a Windows service. The default is `.`. Note that this only controls messages sent from `pg_ctl` itself; once started, the server will use the event source specified by its `event_source` parameter. Should the server fail very early in startup, before that parameter has been set, it might also log using the default event source name `.`

`-N servicename`

Name of the system service to register. This name will be used as both the service name and the display name. The default is `.`

`-P password`

Password for the user to run the service as.

`-S start-type`

Start type of the system service. `start-type` can be `auto`, or `demand`, or the first letter of one of these two. If this option is omitted, `auto` is the default.

`-U username`

User name for the user to run the service as. For domain users, use the format `DOMAIN\username`.

## Environment

`PGCTLTIMEOUT`

Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

`PGDATA`

Default data directory location.

Most `pg_ctl` modes require knowing the data directory location; therefore, the `-D` option is required unless `PGDATA` is set.

`pg_ctl`, like most other utilities, also uses the environment variables supported by `libpq` (see Section 34.14).

For additional variables that affect the server, see `postgres`.

## Files

`postmaster.pid`

`pg_ctl` examines this file in the data directory to determine whether the server is currently running.

`postmaster.opts`

If this file exists in the data directory, `pg_ctl` (in `restart` mode) will pass the contents of the file as options to `postgres`, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

## Examples

### Starting the Server

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

## Stopping the Server

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over *how* the server shuts down:

```
$ pg_ctl stop -m smart
```

## Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that by default, `pg_ctl` saves and reuses the command line options that were passed to the previously-running instance. To restart the server using the same options as before, use:

```
$ pg_ctl restart
```

But if `-o` is specified, that replaces any previous options. To restart using port 5433, disabling `fsync` upon restart:

```
$ pg_ctl -o "-F -p 5433" restart
```

## Showing the Server Status

Here is sample status output from `pg_ctl`:

```
$ pg_ctl status
```

```
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433" "-B" "128"
```

The second line is the command that would be invoked in restart mode.

`initdb`, `postgres`

---

# pg\_resetwal

pg\_resetwal — reset the write-ahead log and other control information of a database cluster

## Synopsis

```
pg_resetwal [-f] [-n] [option...] {[-D] datadir}
```

## Description

pg\_resetwal clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. `pg_resetwal` does not use the environment variable `PGDATA`.

If `pg_resetwal` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, and WAL starting address fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative. *Do not* execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

## Options

`-f`  
Force `pg_resetwal` to proceed even if it cannot determine valid data for `pg_control`, as explained above.

`-n`  
The `-n` (no operation) option instructs `pg_resetwal` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetwal` to proceed for real.

`-V`  
`--version`  
Display version information, then exit.

`-?`  
`--help`  
Show help, then exit.

The following options are only needed when `pg_resetwal` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as described below. For values that take numeric arguments, hexadecimal values can be specified by using the prefix `0x`.

`-c xid,xid`  
Manually set the oldest and newest transaction IDs for which the commit time can be retrieved.

A safe value for the oldest transaction ID for which the commit time can be retrieved (first part) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part) can be determined by looking for the numerically greatest file name in the same directory. The file names are in hexadecimal.

`-e xid_epoch`

Manually set the next transaction ID's epoch.

The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetwal`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I and Skytools work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

`-l walfile`

Manually set the WAL starting address.

The WAL starting address should be larger than any WAL segment file name currently existing in the directory `pg_wal` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `00000001000000320000004A` is the largest entry in `pg_wal`, use `-l 00000001000000320000004B` or higher.

### Note

`pg_resetwal` itself looks at the files in `pg_wal` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_wal`, such as entries in an offline archive; or if the contents of `pg_wal` have been lost entirely.

`-m mxid,mxid`

Manually set the next and oldest multitransaction ID.

A safe value for the next multitransaction ID (first part) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536 (0x10000). Conversely, a safe value for the oldest multitransaction ID (second part of `-m`) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. The file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

`-o oid`

Manually set the next OID.

There is no comparably easy way to determine a next OID that's beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

`-O mxoff`

Manually set the next multitransaction offset.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 52352 (0xCC80). The file names are in hexadecimal. There is no simple recipe such as the ones for other options of appending zeroes.

`-x xid`

Manually set the next transaction ID.

A safe value can be determined by looking for the numerically largest file name in the directory `pg_xact` under the data directory, adding one, and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if 0011 is the largest entry in `pg_xact`, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).

## Notes

This command must not be used when the server is running. `pg_resetwal` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetwal` to run. But before you do so, make doubly certain that there is no server process still alive.

`pg_resetwal` works only with servers of the same major version.

## pg\_rewind

`pg_rewind` — synchronize a data directory with another data directory that was forked from it

### Synopsis

```
pg_rewind[option...] { -D | --target-pgdata } directory { --source-pgdata=directory | --source-server=connstr }
```

### Description

`pg_rewind` is a tool for synchronizing a cluster with another copy of the same cluster, after the clusters' timelines have diverged. A typical scenario is to bring an old master server back online after failover as a standby that follows the new master.

The result is equivalent to replacing the target data directory with the source one. Only changed blocks from relation files are copied; all other files are copied in full, including configuration files. The advantage of `pg_rewind` over taking a new base backup, or tools like `rsync`, is that `pg_rewind` does not require reading through unchanged blocks in the cluster. This makes it a lot faster when the database is large and only a small fraction of blocks differ between the clusters.

`pg_rewind` examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster's `pg_wal` directory reaching all the way back to the point of divergence. The point of divergence can be found either on the target timeline, the source timeline, or their common ancestor. In the typical failover scenario where the target cluster was shut down soon after the divergence, this is not a problem, but if the target cluster ran for a long time after the divergence, the old WAL files might no longer be present. In that case, they can be manually copied from the WAL archive to the `pg_wal` directory, or fetched on startup by configuring `recovery.conf`. The use of `pg_rewind` is not limited to failover, e.g. a standby server can be promoted, run some write transactions, and then rewinded to become a standby again.

When the target server is started for the first time after running `pg_rewind`, it will go into recovery mode and replay all WAL generated in the source server after the point of divergence. If some of the WAL was no longer available in the source server when `pg_rewind` was run, and therefore could not be copied by the `pg_rewind` session, it must be made available when the target server is started. This can be done by creating a `recovery.conf` file in the target data directory with a suitable `restore_command`.

`pg_rewind` requires that the target server either has the `wal_log_hints` option enabled in `postgresql.conf` or data checksums enabled when the cluster was initialized with `initdb`. Neither of these are currently on by default. `full_page_writes` must also be set to `on`, but is enabled by default.

### Options

`pg_rewind` accepts the following command-line arguments:

`-D directory`

`--target-pgdata=directory`

This option specifies the target data directory that is synchronized with the source. The target server must be shut down cleanly before running `pg_rewind`

`--source-pgdata=directory`

Specifies the file system path to the data directory of the source server to synchronize the target with. This option requires the source server to be cleanly shut down.

`--source-server=connstr`

Specifies a libpq connection string to connect to the source server to synchronize the target with. The connection must be a normal (non-replication) connection with superuser access. This option requires the source server to be running and not in recovery mode.

-n  
--dry-run  
Do everything except actually modifying the target directory.

-P  
--progress  
Enables progress reporting. Turning this on will deliver an approximate progress report while copying data from the source cluster.

--debug  
Print verbose debugging output that is mostly useful for developers debugging pg\_rewind.

-V  
--version  
Display version information, then exit.

-?  
--help  
Show help, then exit.

## Environment

When `--source-server` option is used, `pg_rewind` also uses the environment variables supported by `libpq` (see Section 34.14).

## Notes

### How it works

The basic idea is to copy all file system-level changes from the source cluster to the target cluster:

1. Scan the WAL log of the target cluster, starting from the last checkpoint before the point where the source cluster's timeline history forked off from the target cluster. For each WAL record, record each data block that was touched. This yields a list of all the data blocks that were changed in the target cluster, after the source cluster forked off.
2. Copy all those changed blocks from the source cluster to the target cluster, either using direct file system access (`--source-pgdata`) or SQL (`--source-server`).
3. Copy all other files such as `pg_xact` and configuration files from the source cluster to the target cluster (everything except the relation files).
4. Apply the WAL from the source cluster, starting from the checkpoint created at failover. (Strictly speaking, `pg_rewind` doesn't apply the WAL, it just creates a backup label file that makes start by replaying all WAL from that checkpoint forward.)

---

## pg\_test\_fsync

`pg_test_fsync` — determine fastest `wal_sync_method` for

### Synopsis

```
pg_test_fsync [option...]
```

### Description

`pg_test_fsync` is intended to give you a reasonable idea of what the fastest `wal_sync_method` is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by `pg_test_fsync` might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their write-ahead logs. `pg_test_fsync` reports average file sync operation time in microseconds for each `wal_sync_method`, which can also be used to inform efforts to optimize the value of `commit_delay`.

### Options

`pg_test_fsync` accepts the following command-line options:

- `-f`  
`--filename`  
Specifies the file name to write test data in. This file should be in the same file system that the `pg_wal` directory is or will be placed in. (`pg_wal` contains the WAL files.) The default is `pg_test_fsync.out` in the current directory.
- `-s`  
`--secs-per-test`  
Specifies the number of seconds for each test. The more time per test, the greater the test's accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.
- `-V`  
`--version`  
Print the `pg_test_fsync` version and exit.
- `-?`  
`--help`  
Show help about `pg_test_fsync` command line arguments, and exit.

# pg\_test\_timing

pg\_test\_timing — measure timing overhead

## Synopsis

pg\_test\_timing [*option...*]

## Description

pg\_test\_timing is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate EXPLAIN ANALYZE results.

## Options

pg\_test\_timing accepts the following command-line options:

-d *duration*

--duration=*duration*

Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

-V

--version

Print the pg\_test\_timing version and exit.

-?

--help

Show help about pg\_test\_timing command line arguments, and exit.

## Usage

### Interpreting results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system using a TSC clock source shows excellent performance:

Testing timing overhead for 3 seconds.

Per loop time including overhead: 35.96 ns

Histogram of timing durations:

< us	% of total	count
1	96.40465	80435604
2	3.59518	2999652
4	0.00015	126
8	0.00002	13
16	0.00000	2

Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (ns), while the individual timing calls can only resolve down to one microsecond (us).

### Measuring executor timing overhead

When the query executor is running a statement using EXPLAIN ANALYZE, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the psql program:

```
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

## Changing time sources

On some newer Linux systems, it's possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 ns
Histogram of timing durations:
  < us    % of total    count
    1     27.84870    1155682
    2     72.05956    2990371
    4      0.07810     3241
    8      0.01357      563
   16      0.00007       3
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That's 1061 ns of timing overhead, again a small multiple of what's measured directly by this utility. That much timing overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any `EXPLAIN ANALYZE` totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you'll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it's backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
```

< us	% of total	count
1	90.23734	27694571
2	9.75277	2993204
4	0.00981	3010
8	0.00007	22
16	0.00000	1
32	0.00000	1

## Clock hardware and timing accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.

The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It's the preferred way to track the system time when it's supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that's inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn't default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it's known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it's available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the `acpi_pm`. The clock derived from `acpi_pm` will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

# pg\_upgrade

pg\_upgrade — upgrade a server instance

## Synopsis

```
pg_upgrade -b oldbindir -B newbindir -d olddatadir -D newdatadir [option...]
```

## Description

pg\_upgrade (formerly called pg\_migrator) allows data stored in PostgreSQL or data files to be upgraded to a later major version without the data dump/reload typically required for major version upgrades, e.g. from 9.6.3 to the current major release of . It is not required for minor version upgrades, e.g. from 9.6.2 to 9.6.3.

Major releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg\_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg\_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg\_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g. by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg\_upgrade.

pg\_upgrade supports upgrades from 8.4.X and later to the current major release of , including snapshot and beta releases.

## Options

pg\_upgrade accepts the following command-line arguments:

`-b bindir`

`--old-bindir=bindir`

the old executable directory; environment variable `PGBINOLD`

`-B bindir`

`--new-bindir=bindir`

the new executable directory; environment variable `PGBINNEW`

`-c`

`--check`

check clusters only, don't change any data

`-d datadir`

`--old-datadir=datadir`

the old cluster data directory; environment variable `PGDATAOLD`

`-D datadir`

`--new-datadir=datadir`

the new cluster data directory; environment variable `PGDATANEW`

`-j`

`--jobs`

number of simultaneous processes or threads to use

`-k`  
`--link`  
use hard links instead of copying files to the new cluster

`-o options`  
`--old-options options`  
options to be passed directly to the old `postgres` command; multiple option invocations are appended

`-O options`  
`--new-options options`  
options to be passed directly to the new `postgres` command; multiple option invocations are appended

`-p port`  
`--old-port=port`  
the old cluster port number; environment variable `PGPORTOLD`

`-P port`  
`--new-port=port`  
the new cluster port number; environment variable `PGPORTNEW`

`-r`  
`--retain`  
retain SQL and log files even after successful completion

`-U username`  
`--username=username`  
cluster's install user name; environment variable `PGUSER`

`-v`  
`--verbose`  
enable verbose internal logging

`-V`  
`--version`  
display version information, then exit

`-?`  
`--help`  
show help, then exit

## Usage

These are the steps to perform an upgrade with `pg_upgrade`:

### 1. **Optionally move the old cluster**

If you are using a version-specific installation directory, e.g. `/opt/PostgreSQL/10`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

If your installation directory is not version-specific, e.g. `/usr/local/pgsql`, it is necessary to move the current install directory so it does not interfere with the new installation. Once the current server is shut down, it is safe to rename the installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:

```
mv /usr/local/pgsql /usr/local/pgsql.old
```

to rename the directory.

**2. For source installs, build the new version**

Build the new source with `configure` flags that are compatible with the old cluster. `pg_upgrade` will check `pg_controldata` to make sure all settings are compatible before starting the upgrade.

**3. Install the new binaries**

Install the new server's binaries and support files. `pg_upgrade` is included in a default installation.

For source installs, if you wish to install the new server in a custom location, use the `prefix` variable:

```
make prefix=/usr/local/pgsql.new install
```

**4. Initialize the new cluster**

Initialize the new cluster using `initdb`. Again, use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

**5. Install custom shared object files**

Install any custom shared object files (or DLLs) used by the old cluster into the new cluster, e.g. `pgcrypto.so`, whether they are from `contrib` or some other source. Do not install the schema definitions, e.g. `CREATE EXTENSION pgcrypto`, because these will be upgraded from the old cluster. Also, any custom full text search files (dictionary, synonym, thesaurus, stop words) must also be copied to the new cluster.

**6. Adjust authentication**

`pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see Section 34.15).

**7. Stop both servers**

Make sure both database servers are stopped using, on Unix, e.g.:

```
pg_ctl -D /opt/PostgreSQL/9.6 stop
pg_ctl -D /opt/PostgreSQL/10 stop
```

or on Windows, using the proper service names:

```
NET STOP postgresql-9.6
NET STOP postgresql-10
```

Streaming replication and log-shipping standby servers can remain running until a later step.

**8. Prepare for standby server upgrades**

If you are upgrading standby servers using methods outlined in section Step 10, verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the "Latest checkpoint location" values match in all clusters. (There will be a mismatch if old standby servers were shut down before the old primary.) Also, change `wal_level` to `replica` in the `postgresql.conf` file on the new primary cluster.

**9. Run pg\_upgrade**

Always run the `pg_upgrade` binary of the new server, not the old one. `pg_upgrade` requires the specification of the old and new cluster's data and executable (`bin`) directories. You can also specify user and port values, and whether you want the data files linked instead of the default copy behavior.

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and `pg_wal` can be on different file systems.) See `pg_upgrade --help` for a full list of options.

The `--jobs` option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the `postgres` user and set the proper path:

```
RUNAS /USER:postgres "CMD.EXE"  
SET PATH=%PATH%;C:\Program Files\PostgreSQL\10\bin;
```

and then run `pg_upgrade` with quoted directories, e.g.:

```
pg_upgrade.exe  
  --old-datadir "C:/Program Files/PostgreSQL/9.6/data"  
  --new-datadir "C:/Program Files/PostgreSQL/10/data"  
  --old-bindir "C:/Program Files/PostgreSQL/9.6/bin"  
  --new-bindir "C:/Program Files/PostgreSQL/10/bin"
```

Once started, `pg_upgrade` will verify the two clusters are compatible and then do the upgrade. You can use `pg_upgrade --check` to perform only the checks, even if the old server is still running. `pg_upgrade --check` will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link mode, you should use the `--link` option with `--check` to enable link-mode-specific checks. `pg_upgrade` requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. `pg_upgrade` defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, `pg_upgrade` will exit and you will have to revert to the old cluster as outlined in Step 16 below. To try `pg_upgrade` again, you will need to modify the old cluster so the `pg_upgrade` schema restore succeeds. If the problem is a `contrib` module, you might need to uninstall the `contrib` module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

## 10. Upgrade Streaming Replication and Log-Shipping standby servers

If you used link mode and have Streaming Replication (see Section 27.2.5) or Log-Shipping (see Section 27.2) standby servers, you can follow these steps to quickly upgrade them. You will not be running `pg_upgrade` on the standby servers, but rather `rsync` on the primary. Do not start any servers yet.

If you did *not* use link mode, do not have or do not want to use `rsync`, or want an easier solution, skip the instructions in this section and simply recreate the standby servers once `pg_upgrade` completes and the new primary is running.

### a. Install the new binaries on standby servers

Make sure the new binaries and support files are installed on all standby servers.

### b. Make sure the new standby data directories do *not* exist

Make sure the new standby data directories do *not* exist or are empty. If `initdb` was run, delete the standby servers' new data directories.

### c. Install custom shared object files

Install the same custom shared object files on the new standbys that you installed in the new primary cluster.

### d. Stop standby servers

If the standby servers are still running, stop them now using the above instructions.

### e. Save configuration files

Save any configuration files from the old standbys' data directories you need to keep, e.g. `postgresql.conf`, `recovery.conf`, because these will be overwritten or removed in the next step.

**f. Run rsync**

When using link mode, standby servers can be quickly upgraded using rsync. To accomplish this, from a directory on the primary server that is above the old and new database cluster directories, run this on the *primary* for each standby server:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive old_pgdata
    new_pgdata remote_dir
```

where `old_pgdata` and `new_pgdata` are relative to the current directory on the primary, and `remote_dir` is *above* the old and new cluster directories on the standby. The directory structure under the specified directories on the primary and standbys must match. Consult the rsync manual page for details on specifying the remote directory, e.g.

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/
PostgreSQL/9.5/data \
    /opt/PostgreSQL/9.6/data standby.example.com:/opt/PostgreSQL
```

You can verify what the command will do using rsync's `--dry-run` option. While rsync must be run on the primary for at least one standby, it is possible to run rsync on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.

What this does is to record the links created by `pg_upgrade`'s link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby's old cluster and creates links for them in the standby's new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides rapid standby upgrades. Unfortunately, rsync needlessly copies files associated with temporary and unlogged tables because these files don't normally exist on standby servers.

If you have tablespaces, you will need to run a similar rsync command for each tablespace directory, e.g.:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /vol1/
pg_tblsp/PG_9.5_201510051 \
    /vol1/pg_tblsp/PG_9.6_201608131 standby.example.com:/vol1/pg_tblsp
```

If you have relocated `pg_wal` outside the data directories, rsync must be run on those directories too.

**g. Configure streaming replication and log-shipping standby servers**

Configure the servers for log shipping. (You do not need to run `pg_start_backup()` and `pg_stop_backup()` or take a file system backup as the standbys are still synchronized with the primary.)

**11. Restore `pg_hba.conf`**

If you modified `pg_hba.conf`, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g. `postgresql.conf`.

**12. Start the new server**

The new server can now be safely started, and then any rsync'ed standby servers.

**13. Post-Upgrade processing**

If any post-upgrade processing is required, `pg_upgrade` will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```
psql --username=postgres --file=script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

## Caution

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

### 14. Statistics

Because optimizer statistics are not transferred by `pg_upgrade`, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.

### 15. Delete old cluster

Once you are satisfied with the upgrade, you can delete the old cluster's data directories by running the script mentioned when `pg_upgrade` completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g. `bin`, `share`).

### 16. Reverting to old cluster

If, after running `pg_upgrade`, you wish to revert to the old cluster, there are several options:

- If you ran `pg_upgrade` with `--check`, no modifications were made to the old cluster and you can re-use it anytime.
- If you ran `pg_upgrade` with `--link`, the data files are shared between the old and new cluster. If you started the new cluster, the new server has written to those shared files and it is unsafe to use the old cluster.
- If you ran `pg_upgrade` *without* `--link` or did not start the new server, the old cluster was not modified except that, if linking started, a `.old` suffix was appended to `$PGDATA/global/pg_control`. To reuse the old cluster, possibly remove the `.old` suffix from `$PGDATA/global/pg_control`; you can then restart the old cluster.

## Notes

`pg_upgrade` does not support upgrading of databases containing these `reg*` OID-referencing system data types: `regproc`, `regprocedure`, `regoper`, `regoperator`, `regconfig`, and `regdictionary`. (`regtype` can be upgraded.)

All failure, rebuild, and reindex cases will be reported by `pg_upgrade` if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

If you are upgrading a pre-PostgreSQL 9.2 cluster that uses a configuration-file-only directory, you must pass the real data directory location to `pg_upgrade`, and pass the configuration directory location to the server, e.g. `-d /real-data-directory -o '-D /configuration-directory'`.

If using a pre-9.1 old server that is using a non-default Unix-domain socket directory or a default that differs from the default of the new cluster, set `PGHOST` to point to the old server's socket location. (This is not relevant on Windows.)

When performing an upgrade from Postgres Pro 9.6 or lower, for databases with a multibyte encoding, `pg_upgrade` may generate SQL files with `REINDEX/VALIDATE` commands. You must run these files to rebuild indexes and re-validate constraints. This can happen in the following cases:

- The old cluster uses indexes or constraints depending on collations other than the default collation of the database, C, or POSIX.
- On Windows, the old cluster uses indexes or constraints depending on the default collation with a verbose name, such as "Russian\_Russia[.encoding]" or "English\_United States[.encoding]".

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use `rsync` to create a dirty copy of the old cluster while the server is running, then shut down the old server and run `rsync --checksum` again to update the copy with any changes to make it consistent. (`--checksum` is necessary because `rsync` only has file modification-time granularity of one second.) You might want to exclude some files, e.g. `postmaster.pid`, as documented in Section 26.3.3. If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

# pg\_waldump

`pg_waldump` — display a human-readable rendering of the write-ahead log of a database cluster

## Synopsis

```
pg_waldump [option...] [startseg [endseg] ]
```

## Description

`pg_waldump` displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

## Options

The following command-line options control the location and format of the output:

*startseg*

Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

*endseg*

Stop after reading the specified log segment file.

`-b`

`--bkp-details`

Output detailed information about backup blocks.

`-e end`

`--end=end`

Stop reading at the specified WAL location, instead of reading to the end of the log stream.

`-f`

`--follow`

After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

`-n limit`

`--limit=limit`

Display the specified number of records, then stop.

`-p path`

`--path=path`

Specifies a directory to search for log segment files or a directory with a `pg_wal` subdirectory that contains such files. The default is to search in the current directory, the `pg_wal` subdirectory of the current directory, and the `pg_wal` subdirectory of `PGDATA`.

`-r rmgr`

`--rmgr=rmgr`

Only display records generated by the specified resource manager. If `list` is passed as name, print a list of valid resource manager names, and exit.

`-s start`  
`--start=start`

WAL location at which to start reading. The default is to start reading the first valid log record found in the earliest file found.

`-t timeline`  
`--timeline=timeline`

Timeline from which to read log records. The default is to use the value in `startseg`, if that is specified; otherwise, the default is 1.

`-V`  
`--version`

Print the `pg_waldump` version and exit.

`-x xid`  
`--xid=xid`

Only display records marked with the given transaction ID.

`-z`  
`--stats[=record]`

Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

`-?`  
`--help`

Show help about `pg_waldump` command line arguments, and exit.

## Notes

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

`pg_waldump` cannot read WAL files with suffix `.partial`. If those files need to be read, `.partial` suffix needs to be removed from the file name.

# postgres

postgres — database server

## Synopsis

```
postgres [option...]
```

## Description

`postgres` is the database server. In order for a client application to access a database it connects (over a network or locally) to a running `postgres` instance. The `postgres` instance then starts a separate server process to handle the connection.

One `postgres` instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one `postgres` instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When `postgres` starts it needs to know the location of the data area. The location must be specified by the `-D` option or the `PGDATA` environment variable; there is no default. Typically, `-D` or `PGDATA` points directly to the data area directory created by `initdb`. Other possible file layouts are discussed in Section 20.2.

By default `postgres` starts in the foreground and prints log messages to the standard error stream. In practical applications `postgres` should be started as a background process, perhaps at boot time.

The `postgres` command can also be called in single-user mode. The primary use for this mode is during bootstrapping by `initdb`. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

## Options

`postgres` accepts the following command-line arguments. For a detailed discussion of the options consult Chapter 20. You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable `PGOPTIONS` is set, then libpq-based clients will pass that string to the server, which will interpret it as `postgres` command-line options.

## General Purpose

`-B nbuffers`

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `shared_buffers` configuration parameter.

`-c name=value`

Sets a named run-time parameter. The configuration parameters supported by are described in Chapter 20. Most of the other command line options are in fact short forms of such a parameter assignment. `-c` can appear multiple times to set multiple parameters.

`-C name`

Prints the value of the named run-time parameter, and exits. (See the `-c` option above for details.) This can be used on a running server, and returns values from `postgresql.conf`, modified by any

parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This option is meant for other programs that interact with a server instance, such as `pg_ctl`, to query configuration parameter values. User-facing applications should instead use `SHOW` or the `pg_settings` view.

`-d debug-level`

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass `-d 0` for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

`-D datadir`

Specifies the file system location of the database configuration files. See Section 20.2 for details.

`-e`

Sets the default date style to “European”, that is `DMY` ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See Section 8.5 for more information.

`-F`

Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the `fsync` configuration parameter. Read the detailed documentation before using this!

`-h hostname`

Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on `localhost`. Specifying this option is equivalent to setting the `listen_addresses` configuration parameter.

`-i`

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via `-h`.

This option is deprecated since it does not allow access to the full functionality of `listen_addresses`. It's usually better to set `listen_addresses` directly.

`-k directory`

Specifies the directory of the Unix-domain socket on which `postgres` is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally `/tmp`, but that can be changed at build time. Specifying this option is equivalent to setting the `unix_socket_directories` configuration parameter.

`-l`

Enables secure connections using SSL. must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to Section 19.9.

`-N max-connections`

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `max_connections` configuration parameter.

`-o extra-options`

The command-line-style arguments specified in *extra-options* are passed to all server processes started by this `postgres` process.

Spaces within *extra-options* are considered to separate arguments, unless escaped with a backslash (`\`); write `\\` to represent a literal backslash. Multiple arguments can also be specified via multiple uses of `-o`.

The use of this option is obsolete; all command-line options for server processes can be specified directly on the `postgres` command line.

`-p port`

Specifies the TCP/IP port or local Unix domain socket file extension on which `postgres` is to listen for connections from client applications. Defaults to the value of the `PGPORT` environment variable, or if `PGPORT` is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or `PGPORT`.

`-s`

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

`-S work-mem`

Specifies the amount of memory to be used by internal sorts and hashes before resorting to temporary disk files. See the description of the `work_mem` configuration parameter in Section 20.4.1.

`-V`

`--version`

Print the postgres version and exit.

`--name=value`

Sets a named run-time parameter; a shorter form of `-c`.

`--describe-config`

This option dumps out the server's internal configuration variables, descriptions, and defaults in tab-delimited `COPY` format. It is designed primarily for use by administration tools.

`-?`

`--help`

Show help about postgres command line arguments, and exit.

## Semi-internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by system developers. Furthermore, these options might change or be removed in a future release without notice.

`-f { s | i | o | b | t | n | m | h }`

Forbids the use of particular scan and join methods: `s` and `i` disable sequential and index scans respectively, `o`, `b` and `t` disable index-only scans, bitmap index scans, and TID scans respectively, while `n`, `m`, and `h` disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the `-fs` and `-fn` options simply discourage the optimizer from using those plan types if it has any other alternative.

- n  
This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.
- O  
Allows the structure of system tables to be modified. This is used by `initdb`.
- P  
Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.
- t *pa[rser] | pl[anner] | e[xecutor]*  
Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the `-s` option.
- T  
This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will stop all other server processes by sending the signal `SIGSTOP`, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.
- v *protocol*  
Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.
- W *seconds*  
A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.

## Options for Single-User Mode

The following options only apply to the single-user mode (see the section called “Single-User Mode”).

- single  
Selects the single-user mode. This must be the first argument on the command line.
- database*  
Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.
- E  
Echo all commands to standard output before executing them.
- j  
Use semicolon followed by two newlines, rather than just newline, as the command entry terminator.
- r *filename*  
Send all server log output to *filename*. This option is only honored when supplied as a command-line option.

## Environment

### PGCLIENTENCODING

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

### PGDATA

Default data directory location

### PGDATESTYLE

Default value of the `DateStyle` run-time parameter. (The use of this environment variable is deprecated.)

### PGPORT

Default port number (preferably set in the configuration file)

## Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see Section 19.4. You might be able to postpone reconfiguring your kernel by decreasing `shared_buffers` to reduce the shared memory consumption of , and/or by reducing `max_connections` to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non- process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

## Notes

The utility command `pg_ctl` can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, *do not* use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in Section 9.26.2 for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGQUIT` to tell subordinate server processes to terminate without normal cleanup. This signal *should not* be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

## Bugs

The `--` options will not work on FreeBSD or OpenBSD. Use `-c` instead. This is a bug in the affected operating systems; a future release of will provide a workaround if this is not fixed.

## Single-User Mode

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with `-D`, or make sure that the environment variable `PGDATA` is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in `psql`. To continue a command across multiple lines, you must type backslash just before each newline except the last one. The backslash and adjacent newline are both dropped from the input command. Note that this will happen even when within a string literal or comment.

But if you use the `-j` command line switch, a single newline does not terminate command entry; instead, the sequence semicolon-newline-newline does. That is, type a semicolon immediately followed by a completely empty line. Backslash-newline is not treated specially in this mode. Again, there is no intelligence about such a sequence appearing within a string literal or comment.

In either input mode, if you type a semicolon that is not just before or part of a command entry terminator, it is considered a command separator. When you do type a command entry terminator, the multiple statements you've entered will be executed as a single transaction.

To quit the session, type EOF (**Control+D**, usually). If you've entered any text since the last command entry terminator, then EOF will be taken as a command entry terminator, and another EOF will be needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-user mode also does not do any background processing, such as automatic checkpoints or replication.

## Examples

To start `postgres` in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 </dev/null &
```

To start `postgres` with a specific port, e.g. 1234:

```
$ postgres -p 1234
```

To connect to this server using `psql`, specify this port with the `-p` option:

```
$ psql -p 1234
```

or set the environment variable `PGPORT`:

```
$ export PGPORT=1234
$ psql
```

Named run-time parameters can be set in either of these styles:

```
$ postgres -c work_mem=1234
```

```
$ postgres --work-mem=1234
```

Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

# Chapter 51. Overview of Internals

## Author

This chapter originated as part of sim98, Stefan Simkovic's Master's Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of . After having read the following sections you should have an idea of how a query is processed. This chapter does not aim to provide a detailed description of the internal operation of , as such a document would be very extensive. Rather, this chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

## 51.1. The Path of a Query

Here we give a short overview of the stages a query has to pass in order to obtain a result.

1. A connection from an application program to the server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.
2. The *parser stage* checks the query transmitted by the application program for correct syntax and creates a *query tree*.
3. The *rewrite system* takes the query tree created by the parser stage and looks for any *rules* (stored in the *system catalogs*) to apply to the query tree. It performs the transformations given in the *rule bodies*.

One application of the rewrite system is in the realization of *views*. Whenever a query against a view (i.e., a *virtual table*) is made, the rewrite system rewrites the user's query to a query that accesses the *base tables* given in the *view definition* instead.

4. The *planner/optimizer* takes the (rewritten) query tree and creates a *query plan* that will be the input to the *executor*.

It does so by first creating all possible *paths* leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the *plan tree* and retrieves rows in the way represented by the plan. The executor makes use of the *storage system* while scanning relations, performs *sorts* and *joins*, evaluates *qualifications* and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of 's internal control and data structures.

## 51.2. How Connections are Established

is implemented using a simple "process per user" client/server model. In this model there is one *client process* connected to exactly one *server process*. As we do not know ahead of time how many connections will be made, we have to use a *master process* that spawns a new server process every time a connection is requested. This master process is called `postgres` and listens at a specified TCP/IP port for incoming connections. Whenever a request for a connection is detected the `postgres` process spawns a new server process. The server tasks communicate with each other using *semaphores* and *shared memory* to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the protocol described in Chapter 53. Many clients are based on the C-language library libpq, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established the client process can send a query to the *backend* (server). The query is transmitted using plain text, i.e., there is no parsing done in the *frontend* (client). The server parses the query, creates an *execution plan*, executes the plan and returns the retrieved rows to the client by transmitting them over the established connection.

## 51.3. The Parser Stage

The *parser stage* consists of two parts:

- The *parser* defined in `gram.y` and `scan.l` is built using the Unix tools bison and flex.
- The *transformation process* does modifications and augmentations to the data structures returned by the parser.

### 51.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a *parse tree* is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools bison and flex.

The *lexer* is defined in the file `scan.l` and is responsible for recognizing *identifiers*, the *SQL key words* etc. For every key word or identifier that is found, a *token* is generated and handed to the parser.

The parser is defined in the file `gram.y` and consists of a set of *grammar rules* and *actions* that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file `scan.l` is transformed to the C source file `scan.c` using the program flex and `gram.y` is transformed to `gram.c` using bison. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time flex or bison is called.

#### Note

The mentioned transformations and compilations are normally done automatically using the *makefiles* shipped with the source distribution.

A detailed description of bison or the grammar rules given in `gram.y` would be beyond the scope of this paper. There are many books and documents dealing with flex and bison. You should be familiar with bison before you start to study the grammar given in `gram.y` otherwise you won't understand what happens there.

### 51.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the *transformation process* takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the *query tree*.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (`BEGIN`, `ROLLBACK`, etc), and these can then be correctly executed without any further analysis. Once we know

that we are dealing with an actual query (such as `SELECT` or `UPDATE`), it is okay to start a transaction if we're not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a `FuncCall` node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a `FuncExpr` or `Aggref` node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

## 51.4. The Rule System

supports a powerful *rule system* for the specification of *views* and ambiguous *view updates*. Originally the rule system consisted of two implementations:

- The first one worked using *row level* processing and was implemented deep in the *executor*. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.
- The second implementation of the rule system is a technique called *query rewriting*. The *rewrite system* is a module that exists between the *parser stage* and the *planner/optimizer*. This technique is still implemented.

The query rewriter is discussed in some detail in Chapter 41, so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

## 51.5. Planner/Optimizer

The task of the *planner/optimizer* is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

### Note

In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory space. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, uses a *Genetic Query Optimizer* (see Chapter 60) when the number of joins exceeds a threshold (see `geqo_threshold`).

The planner's search procedure actually works with data structures called *paths*, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged *plan tree* is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we'll ignore the distinction between paths and plans.

### 51.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction `relation.attribute OPR constant`. If `relation.attribute` happens to match the key of the B-tree

index and `OPR` is one of the operators listed in the index's *operator class*, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query's `ORDER BY` clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- *nested loop join*: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)
- *merge join*: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is more attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.
- *hash join*: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than `geqo_threshold` relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exist a corresponding join clause in the `WHERE` qualification (i.e., for which a restriction like `where rel1.attr1=rel2.attr2` exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When `geqo_threshold` is exceeded, the join sequences considered are determined by heuristics, as described in Chapter 60. Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do *selection* (discarding rows that do not meet a specified Boolean condition) and *projection* (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the `WHERE` clause and computation of required output expressions to the most appropriate nodes of the plan tree.

## 51.6. Executor

The *executor* takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a `MergeJoin` node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to `lefttree`). The new top node (the top node of the left subplan) is, let's say, a `Sort` node and again recursion is needed to obtain an input row. The child node of the `Sort` might be a `SeqScan` node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The `Sort` node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a `NULL` instead of a row), the `Sort` code performs the sort, and

finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The `MergeJoin` node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the `MergeJoin` node returns `NULL` to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. For `SELECT`, the top-level executor code only needs to send each row returned by the query plan tree off to the client. For `INSERT`, each returned row is inserted into the target table specified for the `INSERT`. This is done in a special top-level plan node called `ModifyTable`. (A simple `INSERT ... VALUES` command creates a trivial plan tree consisting of a single `Result` node, which computes just one result row, and `ModifyTable` above it to perform the insertion. But `INSERT ... SELECT` can demand the full power of the executor mechanism.) For `UPDATE`, the planner arranges that each computed row includes all the updated column values, plus the *TID* (tuple ID, or row ID) of the original target row; this data is fed into a `ModifyTable` node, which uses the information to create a new updated row and mark the old row deleted. For `DELETE`, the only column that is actually returned by the plan is the TID, and the `ModifyTable` node simply uses the TID to visit each target row and mark it deleted.

---

# Chapter 52. System Catalogs

The system catalogs are the place where a relational database management system stores schema metadata, such as information about tables and columns, and internal bookkeeping information. 's system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are normally SQL commands to do that. (For example, `CREATE DATABASE` inserts a row into the `pg_database` catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, but many of those have been made available as SQL commands over time, and so the need for direct manipulation of the system catalogs is ever decreasing.

## 52.1. Overview

Table 52.1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

**Table 52.1. System Catalogs**

Catalog Name	Purpose
<code>pg_aggregate</code>	aggregate functions
<code>pg_am</code>	index access methods
<code>pg_amop</code>	access method operators
<code>pg_amproc</code>	access method support procedures
<code>pg_attrdef</code>	column default values
<code>pg_attribute</code>	table columns (“attributes”)
<code>pg_authid</code>	authorization identifiers (roles)
<code>pg_auth_members</code>	authorization identifier membership relationships
<code>pg_cast</code>	casts (data type conversions)
<code>pg_class</code>	tables, indexes, sequences, views (“relations”)
<code>pg_collation</code>	collations (locale information)
<code>pg_constraint</code>	check constraints, unique constraints, primary key constraints, foreign key constraints
<code>pg_conversion</code>	encoding conversion information
<code>pg_database</code>	databases within this database cluster
<code>pg_db_role_setting</code>	per-role and per-database settings
<code>pg_default_acl</code>	default privileges for object types
<code>pg_depend</code>	dependencies between database objects
<code>pg_description</code>	descriptions or comments on database objects
<code>pg_enum</code>	enum label and value definitions
<code>pg_event_trigger</code>	event triggers
<code>pg_extension</code>	installed extensions
<code>pg_foreign_data_wrapper</code>	foreign-data wrapper definitions
<code>pg_foreign_server</code>	foreign server definitions
<code>pg_foreign_table</code>	additional foreign table information
<code>pg_index</code>	additional index information

<b>Catalog Name</b>	<b>Purpose</b>
pg_inherits	table inheritance hierarchy
pg_init_privs	object initial privileges
pg_language	languages for writing functions
pg_largeobject	data pages for large objects
pg_largeobject_metadata	metadata for large objects
pg_namespace	schemas
pg_opclass	access method operator classes
pg_operator	operators
pg_opfamily	access method operator families
pg_partitioned_table	information about partition key of tables
pg_pltemplate	template data for procedural languages
pg_policy	row-security policies
pg_proc	functions and procedures
pg_publication	publications for logical replication
pg_publication_rel	relation to publication mapping
pg_range	information about range types
pg_replication_origin	registered replication origins
pg_rewrite	query rewrite rules
pg_seclabel	security labels on database objects
pg_sequence	information about sequences
pg_shdepend	dependencies on shared objects
pg_shdescription	comments on shared objects
pg_shseclabel	security labels on shared database objects
pg_statistic	planner statistics
pg_statistic_ext	extended planner statistics
pg_subscription	logical replication subscriptions
pg_subscription_rel	relation state for subscriptions
pg_tablespace	tablespaces within this database cluster
pg_transform	transforms (data type to procedural language conversions)
pg_trigger	triggers
pg_ts_config	text search configurations
pg_ts_config_map	text search configurations' token mappings
pg_ts_dict	text search dictionaries
pg_ts_parser	text search parsers
pg_ts_template	text search templates
pg_type	data types
pg_user_mapping	mappings of users to foreign servers

## 52.2. pg\_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

**Table 52.2. `pg_aggregate` Columns**

Name	Type	References	Description
<code>aggfnoid</code>	<code>regproc</code>	<code>pg_proc .oid</code>	<code>pg_proc</code> OID of the aggregate function
<code>aggkind</code>	<code>char</code>		Aggregate kind: <code>n</code> for “normal” aggregates, <code>o</code> for “ordered-set” aggregates, or <code>h</code> for “hypothetical-set” aggregates
<code>aggnumdirectargs</code>	<code>int2</code>		Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to <code>pronargs</code> , the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates.
<code>aggtransfn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Transition function
<code>aggfinalfn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Final function (zero if none)
<code>aggcombinefn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Combine function (zero if none)
<code>aggserialfn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Serialization function (zero if none)
<code>aggdeserialfn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Deserialization function (zero if none)
<code>aggmtransfn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Forward transition function for moving-aggregate mode (zero if none)
<code>aggminvtransfn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Inverse transition function for moving-aggregate mode (zero if none)
<code>aggmfinalfn</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Final function for moving-aggregate mode (zero if none)
<code>aggfinalextra</code>	<code>bool</code>		True to pass extra dummy arguments to <code>aggfinalfn</code>

Name	Type	References	Description
aggmfinalextra	bool		True to pass extra dummy arguments to <code>aggmfinalfn</code>
aggstortop	oid	<code>pg_operator</code> .oid	Associated sort operator (zero if none)
aggtranstype	oid	<code>pg_type</code> .oid	Data type of the aggregate function's internal transition (state) data
aggtransspace	int4		Approximate average size (in bytes) of the transition state data, or zero to use a default estimate
aggmtranstype	oid	<code>pg_type</code> .oid	Data type of the aggregate function's internal transition (state) data for moving-aggregate mode (zero if none)
aggmtransspace	int4		Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate
agginitval	text		The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.
aggminitval	text		The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.

New aggregate functions are registered with the `CREATE AGGREGATE` command. See Section 38.10 for more information about writing aggregate functions and the meaning of the transition functions, etc.

## 52.3. `pg_am`

The catalog `pg_am` stores information about relation access methods. There is one row for each access method supported by the system. Currently, only indexes have access methods. The requirements for index access methods are discussed in detail in Chapter 61.

**Table 52.3. pg\_am Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
amname	name		Name of the access method
amhandler	regproc	pg_proc .oid	OID of a handler function that is responsible for supplying information about the access method
amtype	char		Currently always <code>i</code> to indicate an index access method; other values may be allowed in future

**Note**

Before 9.6, `pg_am` contained many additional columns representing properties of index access methods. That data is now only directly visible at the C code level. However, `pg_index_column_has_property()` and related functions have been added to allow SQL queries to inspect index access method properties; see Table 9.63.

**52.4. pg\_amop**

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a *search* operator or an *ordering* operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

**Table 52.4. pg\_amop Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
amopfamily	oid	pg_opfamily .oid	The operator family this entry is for
amoplefttype	oid	pg_type .oid	Left-hand input data type of operator
amoprightrighttype	oid	pg_type .oid	Right-hand input data type of operator
amopstrategy	int2		Operator strategy number
amoppurpose	char		Operator purpose, either <code>s</code> for search or <code>o</code> for ordering
amopopr	oid	pg_operator .oid	OID of the operator

Name	Type	References	Description
amopmethod	oid	pg_am .oid	Index access method operator family is for
amopsortfamily	oid	pg_opfamily .oid	The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying `WHERE indexed_column operator constant`. Obviously, such an operator must return boolean, and its left-hand input type must match the index's column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by `ORDER BY indexed_column operator constant`. Such an operator could return any sortable data type, though again its left-hand input type must match the index's column data type. The exact semantics of the `ORDER BY` are specified by the `amopsortfamily` column, which must reference a B-tree operator family for the operator's result type.

### Note

At present, it's assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., `ASC NULLS LAST`. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry's `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprightrighttype` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

## 52.5. pg\_amproc

The catalog `pg_amproc` stores information about support procedures associated with access method operator families. There is one row for each support procedure belonging to an operator family.

**Table 52.5. pg\_amproc Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
amprocfamily	oid	pg_opfamily .oid	The operator family this entry is for
amproclefttype	oid	pg_type .oid	Left-hand input data type of associated operator
amprocrightrighttype	oid	pg_type .oid	Right-hand input data type of associated operator
amprocnum	int2		Support procedure number
amproc	regproc	pg_proc .oid	OID of the procedure

The usual interpretation of the `amproclefttype` and `amprocrightrighttype` fields is that they identify the left and right input types of the operator(s) that a particular support procedure supports. For some access methods these match the input data type(s) of the support procedure itself, for others not. There

is a notion of “default” support procedures for an index, which are those with `amproclefttype` and `amprocrighttype` both equal to the index operator class's `opcintype`.

## 52.6. pg\_attrdef

The catalog `pg_attrdef` stores column default values. The main information about columns is stored in `pg_attribute` (see below). Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

**Table 52.6. pg\_attrdef Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>adrelid</code>	<code>oid</code>	<code>pg_class .oid</code>	The table this column belongs to
<code>adnum</code>	<code>int2</code>	<code>pg_attribute .attnum</code>	The number of the column
<code>adbin</code>	<code>pg_node_tree</code>		The internal representation of the column default value
<code>adsrc</code>	<code>text</code>		A human-readable representation of the default value

The `adsrc` field is historical, and is best not used, because it does not track outside changes that might affect the representation of the default value. Reverse-compiling the `adbin` field (with `pg_get_expr` for example) is a better way to display the default value.

## 52.7. pg\_attribute

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

**Table 52.7. pg\_attribute Columns**

Name	Type	References	Description
<code>attrelid</code>	<code>oid</code>	<code>pg_class .oid</code>	The table this column belongs to
<code>attname</code>	<code>name</code>		The column name
<code>atttypid</code>	<code>oid</code>	<code>pg_type .oid</code>	The data type of this column
<code>attstattarget</code>	<code>int4</code>		<code>attstattarget</code> controls the level of detail of statistics accumulated for this column by <code>ANALYZE</code> . A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive

Name	Type	References	Description
			values is data type-dependent. For scalar data types, <code>attstattarget</code> is both the target number of "most common values" to collect, and the target number of histogram bins to create.
<code>attlen</code>	<code>int2</code>		A copy of <code>pg_type.typelen</code> of this column's type
<code>attnum</code>	<code>int2</code>		The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <code>oid</code> , have (arbitrary) negative numbers.
<code>attndims</code>	<code>int4</code>		Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means "it's an array".)
<code>attcacheoff</code>	<code>int4</code>		Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row
<code>atttypmod</code>	<code>int4</code>		<code>atttypmod</code> records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need <code>atttypmod</code> .
<code>attbyval</code>	<code>bool</code>		A copy of <code>pg_type.typbyval</code> of this column's type
<code>attstorage</code>	<code>char</code>		Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.

Name	Type	References	Description
attalign	char		A copy of <code>pg_type.typalign</code> of this column's type
attnotnull	bool		This represents a not-null constraint.
atthasdef	bool		This column has a default value, in which case there will be a corresponding entry in the <code>pg_attrdef</code> catalog that actually defines the value.
attidentity	char		If a zero byte (''), then not an identity column. Otherwise, a = generated always, d = generated by default.
attisdropped	bool		This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.
attislocal	bool		This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.
attinhcount	int4		The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.
attcollation	oid	<code>pg_collation .oid</code>	The defined collation of the column, or zero if the column is not of a collatable data type.
attacl	<code>aclitem[]</code>		Column-level access privileges, if any have been granted specifically on this column
attoptions	<code>text[]</code>		Attribute-level options, as "keyword=value" strings
attfdwoptions	<code>text[]</code>		Attribute-level foreign data wrapper options, as "keyword=value" strings

In a dropped column's `pg_attribute` entry, `atttypid` is reset to zero, but `attlen` and the other fields copied from `pg_type` are still valid. This arrangement is needed to cope with the situation where the dropped column's data type was later dropped, and so there is no `pg_type` row anymore. `attlen` and the other fields can be used to interpret the contents of a row of the table.

## 52.8. `pg_authid`

The catalog `pg_authid` contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) can have other roles as members; see `pg_auth_members`.

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

Chapter 22 contains detailed information about user and privilege management.

Because user identities are cluster-wide, `pg_authid` is shared across all databases of a cluster: there is only one copy of `pg_authid` per cluster, not one per database.

**Table 52.8. `pg_authid` Columns**

Name	Type	Description
<code>oid</code>	<code>oid</code>	Row identifier (hidden attribute; must be explicitly selected)
<code>rolname</code>	<code>name</code>	Role name
<code>rolsuper</code>	<code>bool</code>	Role has superuser privileges
<code>rolinherit</code>	<code>bool</code>	Role automatically inherits privileges of roles it is a member of
<code>rolcreatorole</code>	<code>bool</code>	Role can create more roles
<code>rolcreatedb</code>	<code>bool</code>	Role can create databases
<code>rolcanlogin</code>	<code>bool</code>	Role can log in. That is, this role can be given as the initial session authorization identifier
<code>rolreplication</code>	<code>bool</code>	Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
<code>rolbypassrls</code>	<code>bool</code>	Role bypasses every row level security policy, see Section 5.7 for more information.
<code>rolconlimit</code>	<code>int4</code>	For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
<code>rolpassword</code>	<code>text</code>	Password (possibly encrypted); null if none. The format depends on the form of encryption used.
<code>rolvaliduntil</code>	<code>timestampz</code>	Password expiry time (only used for password authentication); null if no expiration

For an MD5 encrypted password, `rolpassword` column will begin with the string `md5` followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user's password concatenated to their user name. For example, if user `joe` has password `xyzyzy`, will store the md5 hash of `xyzyzyjoe`.

If the password is encrypted with SCRAM-SHA-256, it has the format:

```
SCRAM-SHA-256$<iteration count>:<salt>$<StoredKey>:<ServerKey>
```

where *salt*, *StoredKey* and *ServerKey* are in Base64 encoded format. This format is the same as that specified by RFC 5803.

A password that does not follow either of those formats is assumed to be unencrypted.

## 52.9. pg\_auth\_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

**Table 52.9. pg\_auth\_members Columns**

Name	Type	References	Description
<code>roleid</code>	<code>oid</code>	<code>pg_authid .oid</code>	ID of a role that has a member
<code>member</code>	<code>oid</code>	<code>pg_authid .oid</code>	ID of a role that is a member of <code>roleid</code>
<code>grantor</code>	<code>oid</code>	<code>pg_authid .oid</code>	ID of the role that granted this membership
<code>admin_option</code>	<code>bool</code>		True if <code>member</code> can grant membership in <code>roleid</code> to others

## 52.10. pg\_cast

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that “automatic I/O conversion casts”, those performed using a data type's own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

**Table 52.10. pg\_cast Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>castsource</code>	<code>oid</code>	<code>pg_type .oid</code>	OID of the source data type
<code>casttarget</code>	<code>oid</code>	<code>pg_type .oid</code>	OID of the target data type
<code>castfunc</code>	<code>oid</code>	<code>pg_proc .oid</code>	The OID of the function to use to perform this cast. Zero is stored if the cast method doesn't require a function.
<code>castcontext</code>	<code>char</code>		Indicates what contexts the cast can be invoked in. <code>e</code> means only as an ex-

Name	Type	References	Description
			explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases.
<code>castmethod</code>	<code>char</code>		Indicates how the cast is performed. <code>f</code> means that the function specified in the <code>castfunc</code> field is used. <code>i</code> means that the input/output functions are used. <code>b</code> means that the types are binary-coercible, thus no conversion is required.

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

## 52.11. `pg_class`

The catalog `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences (but see also `pg_sequence`), views, materialized views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

**Table 52.11. `pg_class` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>relname</code>	<code>name</code>		Name of the table, index, view, etc.
<code>relnamespace</code>	<code>oid</code>	<code>pg_namespace .oid</code>	The OID of the namespace that contains this relation
<code>reltype</code>	<code>oid</code>	<code>pg_type .oid</code>	The OID of the data type that corresponds to this table's row type, if any (zero for indexes, which have no <code>pg_type</code> entry)

<b>Name</b>	<b>Type</b>	<b>References</b>	<b>Description</b>
reloftype	oid	pg_type .oid	For typed tables, the OID of the underlying composite type, zero for all other relations
relowner	oid	pg_authid .oid	Owner of the relation
relam	oid	pg_am .oid	If this is an index, the access method used (B-tree, hash, etc.)
relfilenode	oid		Name of the on-disk file of this relation; zero means this is a “mapped” relation whose disk file name is determined by low-level state
reltablespace	oid	pg_tablespace .oid	The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. (Not meaningful if the relation has no on-disk file.)
relpages	int4		Size of the on-disk representation of this table in pages (of size <code>BLCKSZ</code> ). This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
reltuples	float4		Number of rows in the table. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
relallvisible	int4		Number of pages that are marked all-visible in the table's visibility map. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands such as <code>CREATE INDEX</code> .
reltoastrelid	oid	pg_class .oid	OID of the TOAST table associated with this table, 0 if none. The TOAST table stores large attributes “out of line” in a secondary table.

<b>Name</b>	<b>Type</b>	<b>References</b>	<b>Description</b>
relhasindex	bool		True if this is a table and it has (or recently had) any indexes
relisshared	bool		True if this table is shared across all databases in the cluster. Only certain system catalogs (such as <code>pg_database</code> ) are shared.
relpersistence	char		p = permanent table, u = unlogged table, t = temporary table
relkind	char		r = ordinary table, i = index, s = sequence, t = TOAST table, v = view, m = materialized view, c = composite type, f = foreign table, p = partitioned table
relnatts	int2		Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <code>pg_attribute</code> . See also <code>pg_attribute.attnum</code> .
relchecks	int2		Number of CHECK constraints on the table; see <code>pg_constraint</code> catalog
relhasoids	bool		True if we generate an OID for each row of the relation
relhaspkey	bool		True if the table has (or once had) a primary key
relhasrules	bool		True if table has (or once had) rules; see <code>pg_rewrite</code> catalog
relhastriggers	bool		True if table has (or once had) triggers; see <code>pg_trigger</code> catalog
relhassubclass	bool		True if table has (or once had) any inheritance children
relrowsecurity	bool		True if table has row level security enabled; see <code>pg_policy</code> catalog
relforcerowsecurity	bool		True if row level security (when enabled) will also apply to table owner; see <code>pg_policy</code> catalog

Name	Type	References	Description
relispopulated	bool		True if relation is populated (this is true for all relations other than some materialized views)
relreplident	char		Columns used to form “replica identity” for rows: d = default (primary key, if any), n = nothing, f = all columns i = index with indisreplident set, or default
relispartition	bool		True if table is a partition
relfrozenxid	xid		All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code> to be shrunk. Zero ( <code>InvalidTransactionId</code> ) if the relation is not a table.
relminmxid	xid		All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. Zero ( <code>InvalidMultiXactId</code> ) if the relation is not a table.
relacl	aclitem[]		Access privileges; see GRANT and REVOKE for details
reloptions	text[]		Access-method-specific options, as “keyword=value” strings
relpartbound	pg_node_tree		If table is a partition (see <code>relispartition</code> ), internal representation of the partition bound

Several of the Boolean flags in `pg_class` are maintained lazily: they are guaranteed to be true if that's the correct state, but may not be reset to false immediately when the condition is no longer true. For example, `relhasindex` is set by `CREATE INDEX`, but it is never cleared by `DROP INDEX`. Instead, `VACUUM`

clears `relhasindex` if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

## 52.12. `pg_collation`

The catalog `pg_collation` describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See Section 24.2 for more information.

**Table 52.12. `pg_collation` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>collname</code>	<code>name</code>		Collation name (unique per namespace and encoding)
<code>collnamespace</code>	<code>oid</code>	<code>pg_namespace.oid</code>	The OID of the namespace that contains this collation
<code>collowner</code>	<code>oid</code>	<code>pg_authid.oid</code>	Owner of the collation
<code>collprovider</code>	<code>char</code>		Provider of the collation: <code>d</code> = database default, <code>c</code> = libc, <code>i</code> = icu
<code>collencoding</code>	<code>int4</code>		Encoding in which the collation is applicable, or -1 if it works for any encoding
<code>collcollate</code>	<code>name</code>		<code>LC_COLLATE</code> for this collation object
<code>collctype</code>	<code>name</code>		<code>LC_CTYPE</code> for this collation object
<code>collversion</code>	<code>text</code>		Provider-specific version of the collation. This is recorded when the collation is created and then checked when it is used, to detect changes in the collation definition that could lead to data corruption.

Note that the unique key on this catalog is (`collname`, `collencoding`, `collnamespace`) not just (`collname`, `collnamespace`). `pg_collation` generally ignores all collations that do not have `collencoding` equal to either the current database's encoding or -1, and creation of new entries with the same name as an entry with `collencoding = -1` is forbidden. Therefore it is sufficient to use a qualified SQL name (`schema.name`) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that `initdb` fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the `template0` database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from `template0`. This would currently have to be done manually.

## 52.13. pg\_constraint

The catalog `pg_constraint` stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the `pg_attribute` catalog, not here.

User-defined constraint triggers (created with `CREATE CONSTRAINT TRIGGER`) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

**Table 52.13. pg\_constraint Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
conname	name		Constraint name (not necessarily unique!)
connamespace	oid	<code>pg_namespace .oid</code>	The OID of the namespace that contains this constraint
contype	char		c = check constraint, f = foreign key constraint, p = primary key constraint, u = unique constraint, t = constraint trigger, x = exclusion constraint
condeferrable	bool		Is the constraint deferrable?
condeferred	bool		Is the constraint deferred by default?
convalidated	bool		Has the constraint been validated? Currently, can only be false for foreign keys and CHECK constraints
conrelid	oid	<code>pg_class .oid</code>	The table this constraint is on; 0 if not a table constraint
contypid	oid	<code>pg_type .oid</code>	The domain this constraint is on; 0 if not a domain constraint
conindid	oid	<code>pg_class .oid</code>	The index supporting this constraint, if it's a unique, primary key, foreign key, or exclusion constraint; else 0
confrelid	oid	<code>pg_class .oid</code>	If a foreign key, the referenced table; else 0
confupdtype	char		Foreign key update action code: a = no action, r = restrict, c = cascade,

Name	Type	References	Description
			n = set null, d = set default
confdeltype	char		Foreign key deletion action code: a = no action, r = restrict, c = cascade, n = set null, d = set default
confmatchtype	char		Foreign key match type: f = full, p = partial, s = simple
conislocal	bool		This constraint is defined locally for the relation. Note that a constraint can be locally defined and inherited simultaneously.
coninhcount	int4		The number of direct inheritance ancestors this constraint has. A constraint with a nonzero number of ancestors cannot be dropped nor renamed.
connoinherit	bool		This constraint is defined locally for the relation. It is a non-inheritable constraint.
conkey	int2[]	pg_attribute .attnum	If a table constraint (including foreign keys, but not constraint triggers), list of the constrained columns
confkey	int2[]	pg_attribute .attnum	If a foreign key, list of the referenced columns
conpfeqop	oid[]	pg_operator .oid	If a foreign key, list of the equality operators for PK = FK comparisons
conppeqop	oid[]	pg_operator .oid	If a foreign key, list of the equality operators for PK = PK comparisons
conffeqop	oid[]	pg_operator .oid	If a foreign key, list of the equality operators for FK = FK comparisons
conexclop	oid[]	pg_operator .oid	If an exclusion constraint, list of the per-column exclusion operators
conbin	pg_node_tree		If a check constraint, an internal representation of the expression
consrc	text		If a check constraint, a human-readable repre-

Name	Type	References	Description
			sensation of the expression

In the case of an exclusion constraint, `conkey` is only useful for constraint elements that are simple column references. For other cases, a zero appears in `conkey` and the associated index must be consulted to discover the expression that is constrained. (`conkey` thus has the same contents as `pg_index.indkey` for the index.)

### Note

`consrc` is not updated when referenced objects change; for example, it won't track renaming of columns. Rather than relying on this field, it's best to use `pg_get_constraintdef()` to extract the definition of a check constraint.

### Note

`pg_class.relchecks` needs to agree with the number of check-constraint entries found in this table for each relation.

## 52.14. pg\_conversion

The catalog `pg_conversion` describes encoding conversion procedures. See `CREATE CONVERSION` for more information.

**Table 52.14. pg\_conversion Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>conname</code>	<code>name</code>		Conversion name (unique within a namespace)
<code>connamespace</code>	<code>oid</code>	<code>pg_namespace .oid</code>	The OID of the namespace that contains this conversion
<code>conowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the conversion
<code>conforencoding</code>	<code>int4</code>		Source encoding ID
<code>contoencoding</code>	<code>int4</code>		Destination encoding ID
<code>conproc</code>	<code>regproc</code>	<code>pg_proc .oid</code>	Conversion procedure
<code>condefault</code>	<code>bool</code>		True if this is the default conversion

## 52.15. pg\_database

The catalog `pg_database` stores information about the available databases. Databases are created with the `CREATE DATABASE` command. Consult Chapter 23 for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

**Table 52.15. `pg_database` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>datname</code>	<code>name</code>		Database name
<code>datdba</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the database, usually the user who created it
<code>encoding</code>	<code>int4</code>		Character encoding for this database ( <code>pg_encoding_to_char()</code> can translate this number to the encoding name)
<code>datcollate</code>	<code>name</code>		<code>LC_COLLATE</code> for this database
<code>datctype</code>	<code>name</code>		<code>LC_CTYPE</code> for this database
<code>datistemplate</code>	<code>bool</code>		If true, then this database can be cloned by any user with <code>CREATEDB</code> privileges; if false, then only superusers or the owner of the database can clone it.
<code>datallowconn</code>	<code>bool</code>		If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered.
<code>datconnlimit</code>	<code>int4</code>		Sets maximum number of concurrent connections that can be made to this database. -1 means no limit.
<code>datlastsysoid</code>	<code>oid</code>		Last system OID in the database; useful particularly to <code>pg_dump</code>
<code>datfrozenxid</code>	<code>xid</code>		All transaction IDs before this one have been replaced with a permanent ("frozen") transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code>

Name	Type	References	Description
			to be shrunk. It is the minimum of the per-table <code>pg_class.rel-frozenxid</code> values.
<code>datminmxid</code>	<code>xid</code>		All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relminmxid</code> values.
<code>dattablespace</code>	<code>oid</code>	<code>pg_tablespace.oid</code>	The default tablespace for the database. Within this database, all tables for which <code>pg_class.reltablespace</code> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.
<code>datacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details

## 52.16. pg\_db\_role\_setting

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

**Table 52.16. pg\_db\_role\_setting Columns**

Name	Type	References	Description
<code>setdatabase</code>	<code>oid</code>	<code>pg_database.oid</code>	The OID of the database the setting is applicable to, or zero if not database-specific
<code>setrole</code>	<code>oid</code>	<code>pg_authid.oid</code>	The OID of the role the setting is applicable to, or zero if not role-specific
<code>setconfig</code>	<code>text[]</code>		Defaults for run-time configuration variables

## 52.17. pg\_default\_acl

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

**Table 52.17. pg\_default\_acl Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
defaclrole	oid	<code>pg_authid .oid</code>	The OID of the role associated with this entry
defaclnamespace	oid	<code>pg_namespace .oid</code>	The OID of the namespace associated with this entry, or 0 if none
defaclobjtype	char		Type of object this entry is for: <code>r</code> = relation (table, view), <code>s</code> = sequence, <code>f</code> = function, <code>T</code> = type
defaclacl	aclitem[]		Access privileges that this type of object should have on creation

A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace = 0`, and “per-schema” entries that reference a particular schema. If a global entry is present then it *overrides* the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be *added* to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, *not* whatever might be in `pg_default_acl` at the moment. `pg_default_acl` is only consulted during object creation.

## 52.18. pg\_depend

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a database cluster.

**Table 52.18. pg\_depend Columns**

Name	Type	References	Description
classid	oid	<code>pg_class .oid</code>	The OID of the system catalog the dependent object is in
objid	oid	any OID column	The OID of the specific dependent object
objsubid	int4		For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself).

Name	Type	References	Description
			For all other object types, this column is zero.
refclassid	oid	pg_class .oid	The OID of the system catalog the referenced object is in
refobjid	oid	any OID column	The OID of the specific referenced object
refobjsubid	int4		For a table column, this is the column number (the refobjid and refclassid refer to the table itself). For all other object types, this column is zero.
deptype	char		A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

#### DEPENDENCY\_NORMAL (n)

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

#### DEPENDENCY\_AUTO (a)

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

#### DEPENDENCY\_INTERNAL (i)

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not. Example: a trigger that's created to enforce a foreign-key constraint is made internally dependent on the constraint's `pg_constraint` entry.

#### DEPENDENCY\_EXTENSION (e)

The dependent object is a member of the *extension* that is the referenced object (see `pg_extension`). The dependent object can be dropped only via `DROP EXTENSION` on the referenced object. Functionally this dependency type acts the same as an internal dependency, but it's kept separate for clarity and to simplify `pg_dump`.

#### DEPENDENCY\_AUTO\_EXTENSION (x)

The dependent object is not a member of the extension that is the referenced object (and so should not be ignored by `pg_dump`), but cannot function without it and should be dropped when the extension itself is. The dependent object may be dropped on its own as well.

DEPENDENCY\_PIN (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

## 52.19. pg\_description

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

**Table 52.19. pg\_description Columns**

Name	Type	References	Description
<code>objoid</code>	<code>oid</code>	any OID column	The OID of the object this description pertains to
<code>classoid</code>	<code>oid</code>	<code>pg_class .oid</code>	The OID of the system catalog this object appears in
<code>objsubid</code>	<code>int4</code>		For a comment on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
<code>description</code>	<code>text</code>		Arbitrary text that serves as the description of this object

## 52.20. pg\_enum

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`.

**Table 52.20. pg\_enum Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>enumtypeid</code>	<code>oid</code>	<code>pg_type .oid</code>	The OID of the <code>pg_type</code> entry owning this enum value
<code>enumsortorder</code>	<code>float4</code>		The sort position of this enum value within its enum type
<code>enumlabel</code>	<code>name</code>		The textual label for this enum value

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum

type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions  $1..n$ . But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.

## 52.21. `pg_event_trigger`

The catalog `pg_event_trigger` stores event triggers. See Chapter 40 for more information.

**Table 52.21. `pg_event_trigger` Columns**

Name	Type	References	Description
<code>evtname</code>	<code>name</code>		Trigger name (must be unique)
<code>evtevent</code>	<code>name</code>		Identifies the event for which this trigger fires
<code>evtowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the event trigger
<code>evtfoid</code>	<code>oid</code>	<code>pg_proc .oid</code>	The function to be called
<code>evtenabled</code>	<code>char</code>		Controls in which <code>session_replication_role</code> modes the event trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always.
<code>evttags</code>	<code>text[]</code>		Command tags for which this trigger will fire. If <code>NULL</code> , the firing of this trigger is not restricted on the basis of the command tag.

## 52.22. `pg_extension`

The catalog `pg_extension` stores information about the installed extensions. See Section 38.15 for details about extensions.

**Table 52.22. `pg_extension` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>extname</code>	<code>name</code>		Name of the extension
<code>extowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the extension
<code>extnamespace</code>	<code>oid</code>	<code>pg_namespace .oid</code>	Schema containing the extension's exported objects

Name	Type	References	Description
extrelocatable	bool		True if extension can be relocated to another schema
extversion	text		Version name for the extension
extconfig	oid[]	pg_class .oid	Array of regclass OIDs for the extension's configuration table(s), or NULL if none
extcondition	text[]		Array of WHERE-clause filter conditions for the extension's configuration table(s), or NULL if none

Note that unlike most catalogs with a “namespace” column, `extnamespace` is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, `extnamespace` indicates the schema that contains most or all of the extension's objects. If `extrelocatable` is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

## 52.23. pg\_foreign\_data\_wrapper

The catalog `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

**Table 52.23. pg\_foreign\_data\_wrapper Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
fdwname	name		Name of the foreign-data wrapper
fdwowner	oid	pg_authid .oid	Owner of the foreign-data wrapper
fdwhandler	oid	pg_proc .oid	References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided
fdwvalidator	oid	pg_proc .oid	References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided
fdwacl	aclitem[]		Access privileges; see GRANT and REVOKE for details

Name	Type	References	Description
fdwoptions	text[]		Foreign-data wrapper specific options, as “keyword=value” strings

## 52.24. pg\_foreign\_server

The catalog `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

**Table 52.24. pg\_foreign\_server Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
srvname	name		Name of the foreign server
srvowner	oid	pg_authid.oid	Owner of the foreign server
srvfdw	oid	pg_foreign_data_wrapper.oid	OID of the foreign-data wrapper of this foreign server
srvtype	text		Type of the server (optional)
srvversion	text		Version of the server (optional)
srvacl	aclitem[]		Access privileges; see GRANT and REVOKE for details
srvoptions	text[]		Foreign server specific options, as “keyword=value” strings

## 52.25. pg\_foreign\_table

The catalog `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

**Table 52.25. pg\_foreign\_table Columns**

Name	Type	References	Description
ftrelid	oid	pg_class.oid	OID of the <code>pg_class</code> entry for this foreign table
ftserver	oid	pg_foreign_server.oid	OID of the foreign server for this foreign table
ftoptions	text[]		Foreign table options, as “keyword=value” strings

## 52.26. pg\_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in `pg_class`.

**Table 52.26. pg\_index Columns**

<b>Name</b>	<b>Type</b>	<b>References</b>	<b>Description</b>
<code>indexrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The OID of the <code>pg_class</code> entry for this index
<code>indrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The OID of the <code>pg_class</code> entry for the table this index is for
<code>indnatts</code>	<code>int2</code>		The number of columns in the index (duplicates <code>pg_class.relnatts</code> )
<code>indnkeyatts</code>	<code>int2</code>		The number of key columns in the index. "Key columns" are ordinary index columns (as opposed to "included" columns).
<code>indisunique</code>	<code>bool</code>		If true, this is a unique index
<code>indisprimary</code>	<code>bool</code>		If true, this index represents the primary key of the table ( <code>indisunique</code> should always be true when this is true)
<code>indisexclusion</code>	<code>bool</code>		If true, this index supports an exclusion constraint
<code>indimmediate</code>	<code>bool</code>		If true, the uniqueness check is enforced immediately on insertion (irrelevant if <code>indisunique</code> is not true)
<code>indisclustered</code>	<code>bool</code>		If true, the table was last clustered on this index
<code>indisvalid</code>	<code>bool</code>		If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not guaranteed true either.
<code>indcheckxmin</code>	<code>bool</code>		If true, queries must not use the index until the <code>xmin</code> of this <code>pg_index</code> row is below their <code>TransactionXmin</code> event horizon, because the table may contain broken HOT chains with incom-

Name	Type	References	Description
			patible rows that they can see
indisready	bool		If true, the index is currently ready for inserts. False means the index must be ignored by INSERT/UPDATE operations.
indislive	bool		If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)
indisreplident	bool		If true this index has been chosen as “replica identity” using ALTER TABLE ... REPLICA IDENTITY USING INDEX ...
indkey	int2vector	pg_attribute .attnum	This is an array of indnatts values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.
indcollation	oidvector	pg_collation .oid	For each column in the index key, this contains the OID of the collation to use for the index, or zero if the column is not of a collatable data type.
indclass	oidvector	pg_opclass .oid	For each column in the index key, this contains the OID of the operator class to use. See pg_opclass for details.
indoption	int2vector		This is an array of indnatts values that store per-column flag bits. The meaning of the bits is defined by the index's access method.

Name	Type	References	Description
indexprs	pg_node_tree		Expression trees (in <code>nodeToString()</code> representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <code>indkey</code> . Null if all index attributes are simple references.
indpred	pg_node_tree		Expression tree (in <code>nodeToString()</code> representation) for partial index predicate. Null if not a partial index.

## 52.27. pg\_inherits

The catalog `pg_inherits` records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.)

**Table 52.27. pg\_inherits Columns**

Name	Type	References	Description
inhrelid	oid	pg_class .oid	The OID of the child table
inhparent	oid	pg_class .oid	The OID of the parent table
inhseqno	int4		If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1.

## 52.28. pg\_init\_privs

The catalog `pg_init_privs` records information about the initial privileges of objects in the system. There is one entry for each object in the database which has a non-default (non-NULL) initial set of privileges.

Objects can have initial privileges either by having those privileges set when the system is initialized (by `initdb`) or when the object is created during a `CREATE EXTENSION` and the extension script sets initial privileges using the `GRANT` system. Note that the system will automatically handle recording of the privileges during the extension script and that extension authors need only use the `GRANT` and `REVOKE` statements in their script to have the privileges recorded. The `privtype` column indicates if the initial privilege was set by `initdb` or during a `CREATE EXTENSION` command.

Objects which have initial privileges set by `initdb` will have entries where `privtype` is 'i', while objects which have initial privileges set by `CREATE EXTENSION` will have entries where `privtype` is 'e'.

**Table 52.28. pg\_init\_privs Columns**

Name	Type	References	Description
objoid	oid	any OID column	The OID of the specific object
classoid	oid	pg_class .oid	The OID of the system catalog the object is in
objsubid	int4		For a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.
privtype	char		A code defining the type of initial privilege of this object; see text
initprivs	aclitem[]		The initial access privileges; see GRANT and REVOKE for details

## 52.29. pg\_language

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See `CREATE LANGUAGE` and Chapter 42 for more information about language handlers.

**Table 52.29. pg\_language Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
lanname	name		Name of the language
lanowner	oid	pg_authid .oid	Owner of the language
lanispl	bool		This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future.
lanpltrusted	bool		True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.
lanplcallfoid	oid	pg_proc .oid	For noninternal languages this references

Name	Type	References	Description
			the language handler, which is a special function that is responsible for executing all functions that are written in the particular language
laninline	oid	pg_proc .oid	This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.
lanvalidator	oid	pg_proc .oid	This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.
lanacl	aclitem[]		Access privileges; see GRANT and REVOKE for details

## 52.30. pg\_largeobject

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

**Table 52.30. pg\_largeobject Columns**

Name	Type	References	Description
loid	oid	pg_largeobject_metadata.oid	Identifier of the large object that includes this page
pageno	int4		Page number of this page within its large object (counting from zero)
data	bytea		Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and might be less.

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages might be missing, and

might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

## 52.31. `pg_largeobject_metadata`

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

**Table 52.31. `pg_largeobject_metadata` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>lomowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the large object
<code>lomacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details

## 52.32. `pg_namespace`

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

**Table 52.32. `pg_namespace` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>nspname</code>	<code>name</code>		Name of the namespace
<code>nspowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the namespace
<code>nspacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details

## 52.33. `pg_opclass`

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column's data type as their left-hand input.

Operator classes are described at length in Section 38.14.

**Table 52.33. `pg_opclass` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>opcmethod</code>	<code>oid</code>	<code>pg_am .oid</code>	Index access method operator class is for
<code>opcname</code>	<code>name</code>		Name of this operator class

Name	Type	References	Description
opcnamespace	oid	pg_namespace .oid	Namespace of this operator class
opcowner	oid	pg_authid .oid	Owner of the operator class
opcfamily	oid	pg_opfamily .oid	Operator family containing the operator class
opcintype	oid	pg_type .oid	Data type that the operator class indexes
opcdefault	bool		True if this operator class is the default for opcintype
opckeytype	oid	pg_type .oid	Type of data stored in index, or zero if same as opcintype

An operator class's `opcmethod` must match the `opfmeth` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

## 52.34. pg\_operator

The catalog `pg_operator` stores information about operators. See `CREATE OPERATOR` and Section 38.12 for more information.

**Table 52.34. pg\_operator Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
oprname	name		Name of the operator
oprnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this operator
oprowner	oid	pg_authid .oid	Owner of the operator
oprkind	char		b = infix ("both"), l = prefix ("left"), r = postfix ("right")
oprcanmerge	bool		This operator supports merge joins
oprcanhash	bool		This operator supports hash joins
oprleft	oid	pg_type .oid	Type of the left operand
oprright	oid	pg_type .oid	Type of the right operand
oprresult	oid	pg_type .oid	Type of the result
oprcom	oid	pg_operator .oid	Commutator of this operator, if any
oprnegate	oid	pg_operator .oid	Negator of this operator, if any

Name	Type	References	Description
oprcode	regproc	pg_proc .oid	Function that implements this operator
oprrest	regproc	pg_proc .oid	Restriction selectivity estimation function for this operator
oprjoin	regproc	pg_proc .oid	Join selectivity estimation function for this operator

Unused column contain zeroes. For example, `oprleft` is zero for a prefix operator.

## 52.35. pg\_opfamily

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 38.14.

**Table 52.35. pg\_opfamily Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
opfmethod	oid	pg_am .oid	Index access method operator family is for
opfname	name		Name of this operator family
opfnamespace	oid	pg_namespace .oid	Namespace of this operator family
opfowner	oid	pg_authid .oid	Owner of the operator family

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in `pg_amop`, `pg_amproc`, and `pg_opclass`.

## 52.36. pg\_partitioned\_table

The catalog `pg_partitioned_table` stores information about how tables are partitioned.

**Table 52.36. pg\_partitioned\_table Columns**

Name	Type	References	Description
partrelid	oid	pg_class .oid	The OID of the <code>pg_class</code> entry for this partitioned table
partstrat	char		Partitioning strategy; <code>l</code> = list partitioned table, <code>r</code> = range partitioned table
partnatts	int2		The number of columns in partition key

Name	Type	References	Description
partattrs	int2vector	pg_attribute .attnum	This is an array of <code>partnatts</code> values that indicate which table columns are part of the partition key. For example, a value of <code>1 3</code> would mean that the first and the third table columns make up the partition key. A zero in this array indicates that the corresponding partition key column is an expression, rather than a simple column reference.
partclass	oidvector	pg_opclass .oid	For each column in the partition key, this contains the OID of the operator class to use. See <code>pg_opclass</code> for details.
partcollation	oidvector	pg_opclass .oid	For each column in the partition key, this contains the OID of the collation to use for partitioning, or zero if the column is not of a collatable data type.
partexprs	pg_node_tree		Expression trees (in <code>nodeToString()</code> representation) for partition key columns that are not simple column references. This is a list with one element for each zero entry in <code>partattrs</code> . Null if all partition key columns are simple references.

## 52.37. pg\_pltemplate

The catalog `pg_pltemplate` stores “template” information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details.

Unlike most system catalogs, `pg_pltemplate` is shared across all databases of a cluster: there is only one copy of `pg_pltemplate` per cluster, not one per database. This allows the information to be accessible in each database as it is needed.

**Table 52.37. pg\_pltemplate Columns**

Name	Type	Description
tmplname	name	Name of the language this template is for

Name	Type	Description
tmpltrusted	boolean	True if language is considered trusted
tmpldbacreate	boolean	True if language may be created by a database owner
tmplhandler	text	Name of call handler function
tmplinline	text	Name of anonymous-block handler function, or null if none
tmplvalidator	text	Name of validator function, or null if none
tmpllibrary	text	Path of shared library that implements language
tmplacl	aclitem[]	Access privileges for template (not actually used)

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

### Note

It is likely that `pg_pltemplate` will be removed in some future release of , in favor of keeping this knowledge about procedural languages in their respective extension installation scripts.

## 52.38. pg\_policy

The catalog `pg_policy` stores row level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

**Table 52.38. pg\_policy Columns**

Name	Type	References	Description
polname	name		The name of the policy
polrelid	oid	<code>pg_class .oid</code>	The table to which the policy applies
polcmd	char		The command type to which the policy is applied: <code>r</code> for <code>SELECT</code> , <code>a</code> for <code>INSERT</code> , <code>w</code> for <code>UPDATE</code> , <code>d</code> for <code>DELETE</code> , or <code>*</code> for all
polpermissive	boolean		Is the policy permissive or restrictive?
polroles	oid[]	<code>pg_authid .oid</code>	The roles to which the policy is applied
polqual	<code>pg_node_tree</code>		The expression tree to be added to the security barrier qualifications for queries that use the table
polwithcheck	<code>pg_node_tree</code>		The expression tree to be added to the <code>WITH</code>

Name	Type	References	Description
			CHECK qualifications for queries that attempt to add rows to the table

### Note

Policies stored in `pg_policy` are applied only when `pg_class.relrowsecurity` is set for their table.

## 52.39. pg\_proc

The catalog `pg_proc` stores information about functions (or procedures). See CREATE FUNCTION and Section 38.3 for more information.

The table contains data for aggregate functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

**Table 52.39. pg\_proc Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
proname	name		Name of the function
pronamespace	oid	<code>pg_namespace .oid</code>	The OID of the namespace that contains this function
proowner	oid	<code>pg_authid .oid</code>	Owner of the function
prolang	oid	<code>pg_language .oid</code>	Implementation language or call interface of this function
procost	float4		Estimated execution cost (in units of <code>cpu_operator_cost</code> ); if <code>proretset</code> , this is cost per row returned
prorows	float4		Estimated number of result rows (zero if not <code>proretset</code> )
provariadic	oid	<code>pg_type .oid</code>	Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter
protransform	regproc	<code>pg_proc .oid</code>	Calls to this function can be simplified by this other function (see Section 38.9.10)
proisagg	bool		Function is an aggregate function
proiswindow	bool		Function is a window function

Name	Type	References	Description
prosecdef	bool		Function is a security definer (i.e., a “setuid” function)
proleakproof	bool		The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.
proisstrict	bool		Function returns null if any call argument is null. In that case the function won't actually be called at all. Functions that are not “strict” must be prepared to handle null inputs.
proretset	bool		Function returns a set (i.e., multiple values of the specified data type)
provolatile	char		provolatile tells whether the function's result depends only on its input arguments, or is affected by outside factors. It is <i>i</i> for “immutable” functions, which always deliver the same result for the same inputs. It is <i>s</i> for “stable” functions, whose results (for fixed inputs) do not change within a scan. It is <i>v</i> for “volatile” functions, whose results might change at any time. (Use <i>v</i> also for functions with side-effects, so that calls to them cannot get optimized away.)
proparallel	char		proparallel tells whether the function can be safely run in parallel mode. It is <i>s</i> for functions which are safe to run in parallel mode without restriction. It is <i>r</i> for functions which can be run in parallel mode, but their execution is restricted to the paral-

Name	Type	References	Description
			<p>parallel group leader; parallel worker processes cannot invoke these functions. It is <code>u</code> for functions which are unsafe in parallel mode; the presence of such a function forces a serial execution plan.</p>
pronargs	int2		Number of input arguments
pronargdefaults	int2		Number of arguments that have defaults
prorettype	oid	pg_type .oid	Data type of the return value
proargtypes	oidvector	pg_type .oid	<p>An array with the data types of the function arguments. This includes only input arguments (including <code>INOUT</code> and <code>VARIADIC</code> arguments), and thus represents the call signature of the function.</p>
proallargtypes	oid[]	pg_type .oid	<p>An array with the data types of the function arguments. This includes all arguments (including <code>OUT</code> and <code>INOUT</code> arguments); however, if all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <code>proargtypes</code> is subscripted from 0.</p>
proargmodes	char[]		<p>An array with the modes of the function arguments, encoded as <code>i</code> for <code>IN</code> arguments, <code>o</code> for <code>OUT</code> arguments, <code>b</code> for <code>INOUT</code> arguments, <code>v</code> for <code>VARIADIC</code> arguments, <code>t</code> for <code>TABLE</code> arguments. If all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code>.</p>
proargnames	text[]		An array with the names of the function argu-

Name	Type	References	Description
			ments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .
<code>proargdefaults</code>	<code>pg_node_tree</code>		Expression trees (in <code>nodeToString()</code> representation) for default values. This is a list with <code>pronargdefaults</code> elements, corresponding to the last <i>N</i> input arguments (i.e., the last <i>N</i> <code>proargtypes</code> positions). If none of the arguments have defaults, this field will be null.
<code>protrftypes</code>	<code>oid[]</code>		Data type OIDs for which to apply transforms.
<code>prosrc</code>	<code>text</code>		This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.
<code>probin</code>	<code>text</code>		Additional information about how to invoke the function. Again, the interpretation is language-specific.
<code>proconfig</code>	<code>text[]</code>		Function's local settings for run-time configuration variables
<code>proacl</code>	<code>aclitem[]</code>		Access privileges; see GRANT and REVOKE for details

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

## 52.40. `pg_publication`

The catalog `pg_publication` contains all publications created in the database. For more on publications see Section 32.1.

**Table 52.40. `pg_publication` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>pubname</code>	<code>name</code>		Name of the publication
<code>pubowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the publication
<code>puballtables</code>	<code>bool</code>		If true, this publication automatically includes all tables in the database, including any that will be created in the future.
<code>pubinsert</code>	<code>bool</code>		If true, <code>INSERT</code> operations are replicated for tables in the publication.
<code>pubupdate</code>	<code>bool</code>		If true, <code>UPDATE</code> operations are replicated for tables in the publication.
<code>pubdelete</code>	<code>bool</code>		If true, <code>DELETE</code> operations are replicated for tables in the publication.

## 52.41. `pg_publication_rel`

The catalog `pg_publication_rel` contains the mapping between relations and publications in the database. This is a many-to-many mapping. See also Section 52.78 for a more user-friendly view of this information.

**Table 52.41. `pg_publication_rel` Columns**

Name	Type	References	Description
<code>prpubid</code>	<code>oid</code>	<code>pg_publication .oid</code>	Reference to publication
<code>prrelid</code>	<code>oid</code>	<code>pg_class .oid</code>	Reference to relation

## 52.42. `pg_range`

The catalog `pg_range` stores information about range types. This is in addition to the types' entries in `pg_type`.

**Table 52.42. `pg_range` Columns**

Name	Type	References	Description
<code>rngtypid</code>	<code>oid</code>	<code>pg_type .oid</code>	OID of the range type
<code>rngsubtype</code>	<code>oid</code>	<code>pg_type .oid</code>	OID of the element type (subtype) of this range type
<code>rngcollation</code>	<code>oid</code>	<code>pg_collation .oid</code>	OID of the collation used for range comparisons, or 0 if none

Name	Type	References	Description
<code>rngsubopc</code>	<code>oid</code>	<code>pg_opclass .oid</code>	OID of the subtype's operator class used for range comparisons
<code>rngcanonical</code>	<code>regproc</code>	<code>pg_proc .oid</code>	OID of the function to convert a range value into canonical form, or 0 if none
<code>rngsubdiff</code>	<code>regproc</code>	<code>pg_proc .oid</code>	OID of the function to return the difference between two element values as <code>double precision</code> , or 0 if none

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

## 52.43. `pg_replication_origin`

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see Chapter 50.

**Table 52.43. `pg_replication_origin` Columns**

Name	Type	References	Description
<code>roident</code>	<code>Oid</code>		A unique, cluster-wide identifier for the replication origin. Should never leave the system.
<code>roname</code>	<code>text</code>		The external, user defined, name of a replication origin.

## 52.44. `pg_rewrite`

The catalog `pg_rewrite` stores rewrite rules for tables and views.

**Table 52.44. `pg_rewrite` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>rulename</code>	<code>name</code>		Rule name
<code>ev_class</code>	<code>oid</code>	<code>pg_class .oid</code>	The table this rule is for
<code>ev_type</code>	<code>char</code>		Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE
<code>ev_enabled</code>	<code>char</code>		Controls in which <code>session_replication_role</code> modes the rule fires. o =

Name	Type	References	Description
			rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always.
is_instead	bool		True if the rule is an INSTEAD rule
ev_qual	pg_node_tree		Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition
ev_action	pg_node_tree		Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action

### Note

`pg_class.relhasrules` must be true if a table has any rules in this catalog.

## 52.45. pg\_seclabel

The catalog `pg_seclabel` stores security labels on database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see Section 52.83.

See also `pg_shseclabel`, which performs a similar function for security labels of database objects that are shared across a database cluster.

**Table 52.45. pg\_seclabel Columns**

Name	Type	References	Description
objoid	oid	any OID column	The OID of the object this security label pertains to
classoid	oid	<code>pg_class.oid</code>	The OID of the system catalog this object appears in
objsubid	int4		For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
provider	text		The label provider associated with this label.
label	text		The security label applied to this object.

## 52.46. pg\_sequence

The catalog `pg_sequence` contains information about sequences. Some of the information about sequences, such as the name and the schema, is in `pg_class`.

**Table 52.46. `pg_sequence` Columns**

Name	Type	References	Description
<code>seqrelid</code>	<code>oid</code>	<code>pg_class .oid</code>	The OID of the <code>pg_class</code> entry for this sequence
<code>seqtypeid</code>	<code>oid</code>	<code>pg_type .oid</code>	Data type of the sequence
<code>seqstart</code>	<code>int8</code>		Start value of the sequence
<code>seqincrement</code>	<code>int8</code>		Increment value of the sequence
<code>seqmax</code>	<code>int8</code>		Maximum value of the sequence
<code>seqmin</code>	<code>int8</code>		Minimum value of the sequence
<code>seqcache</code>	<code>int8</code>		Cache size of the sequence
<code>seqcycle</code>	<code>bool</code>		Whether the sequence cycles

## 52.47. `pg_shdepend`

The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows to ensure that those objects are unreferenced before attempting to delete them.

See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

**Table 52.47. `pg_shdepend` Columns**

Name	Type	References	Description
<code>dbid</code>	<code>oid</code>	<code>pg_database .oid</code>	The OID of the database the dependent object is in, or zero for a shared object
<code>classid</code>	<code>oid</code>	<code>pg_class .oid</code>	The OID of the system catalog the dependent object is in
<code>objid</code>	<code>oid</code>	any OID column	The OID of the specific dependent object
<code>objsubid</code>	<code>int4</code>		For a table column, this is the column number (the <code>objid</code> and <code>classid</code> refer to the table itself). For all other object types, this column is zero.

Name	Type	References	Description
refclassid	oid	pg_class .oid	The OID of the system catalog the referenced object is in (must be a shared catalog)
refobjid	oid	any OID column	The OID of the specific referenced object
deptype	char		A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

`SHARED_DEPENDENCY_OWNER` (o)

The referenced object (which must be a role) is the owner of the dependent object.

`SHARED_DEPENDENCY_ACL` (a)

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

`SHARED_DEPENDENCY_POLICY` (r)

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

`SHARED_DEPENDENCY_PIN` (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.

## 52.48. pg\_shdescription

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

**Table 52.48. pg\_shdescription Columns**

Name	Type	References	Description
objoid	oid	any OID column	The OID of the object this description pertains to
classoid	oid	pg_class .oid	The OID of the system catalog this object appears in

Name	Type	References	Description
description	text		Arbitrary text that serves as the description of this object

## 52.49. pg\_shseclabel

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the `SECURITY LABEL` command. For an easier way to view security labels, see Section 52.83.

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

**Table 52.49. pg\_shseclabel Columns**

Name	Type	References	Description
objoid	oid	any OID column	The OID of the object this security label pertains to
classoid	oid	<code>pg_class.oid</code>	The OID of the system catalog this object appears in
provider	text		The label provider associated with this label.
label	text		The security label applied to this object.

## 52.50. pg\_statistic

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children, a second entry with `stainherit = true` is also created. This row represents the column's statistics over the inheritance tree, i.e., statistics for the data you'd see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

Since different kinds of statistics might be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in "slots", which are groups of associated columns whose content is identified by a code number in one of the slot's columns. For more information see `src/include/catalog/pg_statistic.h`.

`pg_statistic` should not be readable by the public, since even statistical information about a table's contents might be considered sensitive. (Example: minimum and maximum values of a salary column)

might be quite interesting.) `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

**Table 52.50. `pg_statistic` Columns**

Name	Type	References	Description
<code>starelid</code>	<code>oid</code>	<code>pg_class .oid</code>	The table or index that the described column belongs to
<code>staattnum</code>	<code>int2</code>	<code>pg_attribute .attnum</code>	The number of the described column
<code>stainherit</code>	<code>bool</code>		If true, the stats include inheritance child columns, not just the values in the specified relation
<code>stanullfrac</code>	<code>float4</code>		The fraction of the column's entries that are null
<code>stawidth</code>	<code>int4</code>		The average stored width, in bytes, of non-null entries
<code>stadistinct</code>	<code>float4</code>		The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by <code>stadistinct = -0.4</code> . A zero value means the number of distinct values is unknown.
<code>stakindN</code>	<code>int2</code>		A code number indicating the kind of statistics stored in the <i>N</i> th "slot" of the <code>pg_statistic</code> row.
<code>staopN</code>	<code>oid</code>	<code>pg_operator .oid</code>	An operator used to derive the statistics stored in the <i>N</i> th "slot". For example, a histogram slot would show the <code>&lt;</code> operator that defines the sort order of the data.
<code>stanumbersN</code>	<code>float4[]</code>		Numerical statistics of the appropriate kind for the <i>N</i> th "slot", or null if

Name	Type	References	Description
			the slot kind does not involve numerical values
stavalues $N$	anyarray		Column data values of the appropriate kind for the $N$ th "slot", or null if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, or a related type such as an array's element type, so there is no way to define these columns' type more specifically than anyarray.

## 52.51. pg\_statistic\_ext

The catalog `pg_statistic_ext` holds extended planner statistics. Each row in this catalog corresponds to a *statistics object* created with `CREATE STATISTICS`.

**Table 52.51. pg\_statistic\_ext Columns**

Name	Type	References	Description
stxrelid	oid	pg_class .oid	Table containing the columns described by this object
stxname	name		Name of the statistics object
stxnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this statistics object
stxowner	oid	pg_authid .oid	Owner of the statistics object
stxkeys	int2vector	pg_attribute .attnum	An array of attribute numbers, indicating which table columns are covered by this statistics object; for example a value of 1 3 would mean that the first and the third table columns are covered
stxkind	char[]		An array containing codes for the enabled statistic kinds; valid values are: <code>d</code> for n-distinct statistics, <code>f</code> for functional dependency statistics
stxndistinct	pg_ndistinct		N-distinct counts, serialized as <code>pg_ndistinct</code> type

Name	Type	References	Description
stxdependencies	pg_dependencies		Functional dependency statistics, serialized as <code>pg_dependencies type</code>

The `stxkind` field is filled at creation of the statistics object, indicating which statistic type(s) are desired. The fields after it are initially NULL and are filled only when the corresponding statistic has been computed by `ANALYZE`.

## 52.52. pg\_subscription

The catalog `pg_subscription` contains all existing logical replication subscriptions. For more information about logical replication see Chapter 32.

Unlike most system catalogs, `pg_subscription` is shared across all databases of a cluster: There is only one copy of `pg_subscription` per cluster, not one per database.

Access to the column `subconninfo` is revoked from normal users, because it could contain plain-text passwords.

**Table 52.52. pg\_subscription Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
subdbid	oid	<code>pg_database .oid</code>	OID of the database which the subscription resides in
subname	name		Name of the subscription
subowner	oid	<code>pg_authid .oid</code>	Owner of the subscription
subenabled	bool		If true, the subscription is enabled and should be replicating.
subsynchronouscommit	text		Contains the value of the <code>synchronous_commit</code> setting for the subscription workers.
subconninfo	text		Connection string to the upstream database
subslotname	name		Name of the replication slot in the upstream database. Also used for local replication origin name.
subpublications	text []		Array of subscribed publication names. These reference the publications on the publisher server. For more on publications see Section 32.1.

## 52.53. pg\_subscription\_rel

The catalog `pg_subscription_rel` contains the state for each replicated relation in each subscription. This is a many-to-many mapping.

This catalog only contains tables known to the subscription after running either `CREATE SUBSCRIPTION` or `ALTER SUBSCRIPTION ... REFRESH PUBLICATION`.

**Table 52.53. `pg_subscription_rel` Columns**

Name	Type	References	Description
<code>srsubid</code>	<code>oid</code>	<code>pg_subscription .oid</code>	Reference to subscription
<code>srrelid</code>	<code>oid</code>	<code>pg_class .oid</code>	Reference to relation
<code>srsubstate</code>	<code>char</code>		State code: <code>i</code> = initialize, <code>d</code> = data is being copied, <code>s</code> = synchronized, <code>r</code> = ready (normal replication)
<code>srsublsn</code>	<code>pg_lsn</code>		End LSN for <code>s</code> and <code>r</code> states.

## 52.54. `pg_tablespace`

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

**Table 52.54. `pg_tablespace` Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>spcname</code>	<code>name</code>		Tablespace name
<code>spcowner</code>	<code>oid</code>	<code>pg_authid .oid</code>	Owner of the tablespace, usually the user who created it
<code>spcacl</code>	<code>aclitem[]</code>		Access privileges; see <code>GRANT</code> and <code>REVOKE</code> for details
<code>spcoptions</code>	<code>text[]</code>		Tablespace-level options, as “keyword=value” strings

## 52.55. `pg_transform`

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See `CREATE TRANSFORM` for more information.

**Table 52.55. `pg_transform` Columns**

Name	Type	References	Description
<code>trftype</code>	<code>oid</code>	<code>pg_type .oid</code>	OID of the data type this transform is for

Name	Type	References	Description
trflang	oid	pg_language .oid	OID of the language this transform is for
trffromsql	regproc	pg_proc .oid	The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if this operation is not supported.
trftosql	regproc	pg_proc .oid	The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if this operation is not supported.

## 52.56. pg\_trigger

The catalog `pg_trigger` stores triggers on tables and views. See `CREATE TRIGGER` for more information.

**Table 52.56. pg\_trigger Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
tgrelid	oid	pg_class .oid	The table this trigger is on
tgname	name		Trigger name (must be unique among triggers of same table)
tgfoid	oid	pg_proc .oid	The function to be called
tgtype	int2		Bit mask identifying trigger firing conditions
tgenabled	char		Controls in which session_replication_role modes the trigger fires. <code>O</code> = trigger fires in “origin” and “local” modes, <code>D</code> = trigger is disabled, <code>R</code> = trigger fires in “replica” mode, <code>A</code> = trigger fires always.
tgisinternal	bool		True if trigger is internally generated (usually, to enforce the constraint identified by <code>tg-constraint</code> )

Name	Type	References	Description
tgconstrrelid	oid	pg_class .oid	The table referenced by a referential integrity constraint
tgconstrindid	oid	pg_class .oid	The index supporting a unique, primary key, referential integrity, or exclusion constraint
tgconstraint	oid	pg_constraint .oid	The pg_constraint entry associated with the trigger, if any
tgdeferrable	bool		True if constraint trigger is deferrable
tginitdeferred	bool		True if constraint trigger is initially deferred
tgargs	int2		Number of argument strings passed to trigger function
tgattr	int2vector	pg_attribute .attnum	Column numbers, if trigger is column-specific; otherwise an empty array
tgargs	bytea		Argument strings to pass to trigger, each NULL-terminated
tgqual	pg_node_tree		Expression tree (in nodeToString() representation) for the trigger's WHEN condition, or null if none
tgoldtable	name		REFERENCING clause name for OLD TABLE, or null if none
tgnewtable	name		REFERENCING clause name for NEW TABLE, or null if none

Currently, column-specific triggering is supported only for UPDATE events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

### Note

When `tgconstraint` is nonzero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tginitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

### Note

`pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

## 52.57. pg\_ts\_config

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser's output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`.

's text search features are described at length in Chapter 12.

**Table 52.57. pg\_ts\_config Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
cfgname	name		Text search configuration name
cfgnamespace	oid	<code>pg_namespace .oid</code>	The OID of the namespace that contains this configuration
cfgowner	oid	<code>pg_authid .oid</code>	Owner of the configuration
cfgparser	oid	<code>pg_ts_parser .oid</code>	The OID of the text search parser for this configuration

## 52.58. pg\_ts\_config\_map

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration's parser.

's text search features are described at length in Chapter 12.

**Table 52.58. pg\_ts\_config\_map Columns**

Name	Type	References	Description
mapcfg	oid	<code>pg_ts_config .oid</code>	The OID of the <code>pg_ts_config</code> entry owning this map entry
maptokentype	integer		A token type emitted by the configuration's parser
mapseqno	integer		Order in which to consult this entry (lower <code>mapseqnos</code> first)
mapdict	oid	<code>pg_ts_dict .oid</code>	The OID of the text search dictionary to consult

## 52.59. pg\_ts\_dict

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

's text search features are described at length in Chapter 12.

**Table 52.59. `pg_ts_dict` Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
dictname	name		Text search dictionary name
dictnamespace	oid	<code>pg_namespace .oid</code>	The OID of the namespace that contains this dictionary
dictowner	oid	<code>pg_authid .oid</code>	Owner of the dictionary
dicttemplate	oid	<code>pg_ts_template .oid</code>	The OID of the text search template for this dictionary
dictinitoption	text		Initialization option string for the template

## 52.60. `pg_ts_parser`

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

's text search features are described at length in Chapter 12.

**Table 52.60. `pg_ts_parser` Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
prsname	name		Text search parser name
prsnamespace	oid	<code>pg_namespace .oid</code>	The OID of the namespace that contains this parser
prsstart	regproc	<code>pg_proc .oid</code>	OID of the parser's start-up function
prstoken	regproc	<code>pg_proc .oid</code>	OID of the parser's next-token function
prsend	regproc	<code>pg_proc .oid</code>	OID of the parser's shut-down function
prsheadline	regproc	<code>pg_proc .oid</code>	OID of the parser's headline function
prslextype	regproc	<code>pg_proc .oid</code>	OID of the parser's lex-type function

## 52.61. `pg_ts_template`

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

's text search features are described at length in Chapter 12.

**Table 52.61. pg\_ts\_template Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
tmplname	name		Text search template name
tmplnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this template
tmplinit	regproc	pg_proc .oid	OID of the template's initialization function
tmpllexize	regproc	pg_proc .oid	OID of the template's lexize function

## 52.62. pg\_type

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

**Table 52.62. pg\_type Columns**

Name	Type	References	Description
oid	oid		Row identifier (hidden attribute; must be explicitly selected)
typname	name		Data type name
typnamespace	oid	pg_namespace .oid	The OID of the namespace that contains this type
typowner	oid	pg_authid .oid	Owner of the type
typlen	int2		For a fixed-size type, <code>typlen</code> is the number of bytes in the internal representation of the type. But for a variable-length type, <code>typlen</code> is negative. -1 indicates a "varlena" type (one that has a length word), -2 indicates a null-terminated C string.
typbyval	bool		<code>typbyval</code> determines whether internal routines pass a value of this type by value or by reference. <code>typbyval</code> had better be false if <code>typlen</code> is not 1, 2, or 4 (or 8 on machines where Datum is

Name	Type	References	Description
			8 bytes). Variable-length types are always passed by reference. Note that <code>typbyval</code> can be false even if the length would allow pass-by-value.
typtype	char		typtype is <code>b</code> for a base type, <code>c</code> for a composite type (e.g., a table's row type), <code>d</code> for a domain, <code>e</code> for an enum type, <code>p</code> for a pseudo-type, or <code>r</code> for a range type. See also <code>typrelid</code> and <code>typbase-type</code> .
typcategory	char		typcategory is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be "preferred". See Table 52.63.
typispreferred	bool		True if the type is a preferred cast target within its <code>typcategory</code>
typisdefined	bool		True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When <code>typisdefined</code> is false, nothing except the type name, namespace, and OID can be relied on.
typdelim	char		Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.
typrelid	oid	pg_class .oid	If this is a composite type (see <code>typtype</code> ), then this column points to the <code>pg_class</code> entry that defines the corresponding table. (For a free-standing composite type, the <code>pg_class</code> entry doesn't really represent a table, but it is needed anyway for the type's <code>pg_attribute</code> entries to link

Name	Type	References	Description
			to.) Zero for non-composite types.
typelem	oid	pg_type .oid	If typelem is not 0 then it identifies another row in pg_type . The current type can then be subscripted like an array yielding values of type typelem. A “true” array type is variable length (typlen = -1), but some fixed-length (typlen > 0) types also have nonzero typelem, for example name and point. If a fixed-length type has a typelem then its internal representation must be some number of values of the typelem data type with no other data. Variable-length array types have a header defined by the array subroutines.
typarray	oid	pg_type .oid	If typarray is not 0 then it identifies another row in pg_type , which is the “true” array type having this type as element
typinput	regproc	pg_proc .oid	Input conversion function (text format)
typoutput	regproc	pg_proc .oid	Output conversion function (text format)
typreceive	regproc	pg_proc .oid	Input conversion function (binary format), or 0 if none
typsend	regproc	pg_proc .oid	Output conversion function (binary format), or 0 if none
typmodin	regproc	pg_proc .oid	Type modifier input function, or 0 if type does not support modifiers
typmodout	regproc	pg_proc .oid	Type modifier output function, or 0 to use the standard format
typanalyze	regproc	pg_proc .oid	Custom ANALYZE function, or 0 to use the standard function
typalign	char		typalign is the alignment required when storing a value of this

Name	Type	References	Description
			<p>type. It applies to storage on disk as well as most representations of the value inside . When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence.</p> <p>Possible values are:</p> <ul style="list-style-type: none"> <li>• c = char alignment, i.e., no alignment needed.</li> <li>• s = short alignment (2 bytes on most machines).</li> <li>• i = int alignment (4 bytes on most machines).</li> <li>• d = double alignment (8 bytes on many machines, but by no means all).</li> </ul> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p style="text-align: center;"><b>Note</b></p> <p>For types used in system tables, it is critical that the size and alignment defined in pg_type agree with the way that the compiler will lay out the column in a structure representing a table row.</p> </div>

Name	Type	References	Description
typstorage	char		<p>typstorage tells for varlena types (those with <code>typlen = -1</code>) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are</p> <ul style="list-style-type: none"> <li>• p: Value must always be stored plain.</li> <li>• e: Value can be stored in a “secondary” relation (if relation has one, see <code>pg_class.reltoastrelid</code>).</li> <li>• m: Value can be stored compressed inline.</li> <li>• x: Value can be stored compressed inline or stored in “secondary” storage.</li> </ul> <p>Note that m columns can also be moved out to secondary storage, but only as a last resort (e and x columns are moved first).</p>
typnotnull	bool		<p>typnotnull represents a not-null constraint on a type. Used for domains only.</p>
typbasetype	oid	pg_type .oid	<p>If this is a domain (see <code>typtype</code>), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain.</p>
typtypmod	int4		<p>Domains use <code>typtypmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code>). -1 if this type is not a domain.</p>
typndims	int4		<p>typndims is the number of array dimensions for a domain over an array (that is, <code>typbasetype</code> is an array type). Zero for types other than domains over array types.</p>

Name	Type	References	Description
typcollation	oid	pg_collation .oid	typcollation specifies the collation of the type. If the type does not support collations, this will be zero. A base type that supports collations will have DEFAULT_COLLATION_OID here. A domain over a collatable type can have some other collation OID, if one was specified for the domain.
typdefaultbin	pg_node_tree		If typdefaultbin is not null, it is the nodeToString() representation of a default expression for the type. This is only used for domains.
typdefault	text		typdefault is null if the type has no associated default value. If typdefaultbin is not null, typdefault must contain a human-readable version of the default expression represented by typdefaultbin. If typdefaultbin is null and typdefault is not, then typdefault is the external representation of the type's default value, which can be fed to the type's input converter to produce a constant.
typacl	aclitem[]		Access privileges; see GRANT and REVOKE for details

Table 52.63 lists the system-defined values of `typcategory`. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

**Table 52.63. typcategory Codes**

Code	Category
A	Array types
B	Boolean types
C	Composite types
D	Date/time types
E	Enum types
G	Geometric types

Code	Category
I	Network address types
N	Numeric types
P	Pseudo-types
R	Range types
S	String types
T	Timespan types
U	User-defined types
V	Bit-string types
X	unknown type

## 52.63. pg\_user\_mapping

The catalog `pg_user_mapping` stores the mappings from local user to remote. Access to this catalog is restricted from normal users, use the view `pg_user_mappings` instead.

**Table 52.64. pg\_user\_mapping Columns**

Name	Type	References	Description
<code>oid</code>	<code>oid</code>		Row identifier (hidden attribute; must be explicitly selected)
<code>umuser</code>	<code>oid</code>	<code>pg_authid .oid</code>	OID of the local role being mapped, 0 if the user mapping is public
<code>umserver</code>	<code>oid</code>	<code>pg_foreign_server.oid</code>	The OID of the foreign server that contains this mapping
<code>umoptions</code>	<code>text[]</code>		User mapping specific options, as “key=word=value” strings

## 52.64. System Views

In addition to the system catalogs, provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 37) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are -specific, it's usually better to use the information schema if it provides all the information you need.

Table 52.65 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in Table 29.2.

Except where noted, all the views described here are read-only.

**Table 52.65. System Views**

View Name	Purpose
<code>pg_available_extensions</code>	available extensions

View Name	Purpose
pg_available_extension_versions	available versions of extensions
pg_config	compile-time configuration parameters
pg_cursors	open cursors
pg_file_settings	summary of configuration file contents
pg_group	groups of database users
pg_hba_file_rules	summary of client authentication configuration file contents
pg_indexes	indexes
pg_locks	locks currently held or awaited
pg_matviews	materialized views
pg_policies	policies
pg_prepared_statements	prepared statements
pg_prepared_xacts	prepared transactions
pg_publication_tables	publications and their associated tables
pg_replication_origin_status	information about replication origins, including replication progress
pg_replication_slots	replication slot information
pg_roles	database roles
pg_rules	rules
pg_seclabels	security labels
pg_sequences	sequences
pg_settings	parameter settings
pg_shadow	database users
pg_stats	planner statistics
pg_tables	tables
pg_timezone_abbrevs	time zone abbreviations
pg_timezone_names	time zone names
pg_user	database users
pg_user_mappings	user mappings
pg_views	views

## 52.65. pg\_available\_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 52.66. pg\_available\_extensions Columns**

Name	Type	Description
name	name	Extension name
default_version	text	Name of default version, or NULL if none is specified
installed_version	text	Currently installed version of the extension, or NULL if not installed

Name	Type	Description
comment	text	Comment string from the extension's control file

The `pg_available_extensions` view is read only.

## 52.66. `pg_available_extension_versions`

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

**Table 52.67. `pg_available_extension_versions` Columns**

Name	Type	Description
name	name	Extension name
version	text	Version name
installed	bool	True if this version of this extension is currently installed
superuser	bool	True if only superusers are allowed to install this extension
relocatable	bool	True if extension can be relocated to another schema
schema	name	Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable
requires	name []	Names of prerequisite extensions, or NULL if none
comment	text	Comment string from the extension's control file

The `pg_available_extension_versions` view is read only.

## 52.67. `pg_config`

The view `pg_config` describes the compile-time configuration parameters of the currently installed version of . It is intended, for example, to be used by software packages that want to interface to to facilitate finding the required header files and libraries. It provides the same basic information as the `pg_config` client application.

By default, the `pg_config` view can be read only by superusers.

**Table 52.68. `pg_config` Columns**

Name	Type	Description
name	text	The parameter name
setting	text	The parameter value

## 52.68. `pg_cursors`

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the DECLARE statement in SQL
- via the Bind message in the frontend/backend protocol, as described in Section 53.2.3

- via the Server Programming Interface (SPI), as described in Section 47.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

### Note

Cursors are used internally to implement some of the components of , such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

**Table 52.69. `pg_cursors` Columns**

Name	Type	Description
<code>name</code>	<code>text</code>	The name of the cursor
<code>statement</code>	<code>text</code>	The verbatim query string submitted to declare this cursor
<code>is_holdable</code>	<code>boolean</code>	<code>true</code> if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); <code>false</code> otherwise
<code>is_binary</code>	<code>boolean</code>	<code>true</code> if the cursor was declared <code>BINARY</code> ; <code>false</code> otherwise
<code>is_scrollable</code>	<code>boolean</code>	<code>true</code> if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); <code>false</code> otherwise
<code>creation_time</code>	<code>timestampz</code>	The time at which the cursor was declared

The `pg_cursors` view is read only.

## 52.69. `pg_file_settings`

The view `pg_file_settings` provides a summary of the contents of the server's configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)

By default, the `pg_file_settings` view can be read only by superusers.

**Table 52.70. `pg_file_settings` Columns**

Name	Type	Description
<code>sourcefile</code>	<code>text</code>	Full path name of the configuration file
<code>sourceline</code>	<code>integer</code>	Line number within the configuration file where the entry appears

Name	Type	Description
seqno	integer	Order in which the entries are processed (1..n)
name	text	Configuration parameter name
setting	text	Value to be assigned to the parameter
applied	boolean	True if the value can be applied successfully
error	text	If not null, an error message indicating why this entry could not be applied

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the `applied` fields will read as false. In such a case there will be one or more rows with non-null `error` fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the `error` field. Another way that an entry might have `applied = false` is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the `error` field.

See Section 20.1 for more information about the various ways to change run-time parameters.

## 52.70. pg\_group

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

**Table 52.71. pg\_group Columns**

Name	Type	References	Description
groname	name	<code>pg_authid .rolname</code>	Name of the group
grosysid	oid	<code>pg_authid .oid</code>	ID of this group
grolist	oid[]	<code>pg_authid .oid</code>	An array containing the IDs of the roles in this group

## 52.71. pg\_hba\_file\_rules

The view `pg_hba_file_rules` provides a summary of the contents of the client authentication configuration file, `pg_hba.conf`. A row appears in this view for each non-empty, non-comment line in the file, with annotations indicating whether the rule could be applied successfully.

This view can be helpful for checking whether planned changes in the authentication configuration file will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the file, not on what was last loaded by the server.

By default, the `pg_hba_file_rules` view can be read only by superusers.

**Table 52.72. pg\_hba\_file\_rules Columns**

Name	Type	Description
line_number	integer	Line number of this rule in <code>pg_hba.conf</code>

Name	Type	Description
type	text	Type of connection
database	text []	List of database name(s) to which this rule applies
user_name	text []	List of user and group name(s) to which this rule applies
address	text	Host name or IP address, or one of all, samehost, or samenet, or null for local connections
netmask	text	IP address mask, or null if not applicable
auth_method	text	Authentication method
options	text []	Options specified for authentication method, if any
error	text	If not null, an error message indicating why this line could not be processed

Usually, a row reflecting an incorrect entry will have values for only the `line_number` and `error` fields. See Chapter 21 for more information about client authentication configuration.

## 52.72. pg\_indexes

The view `pg_indexes` provides access to useful information about each index in the database.

**Table 52.73. pg\_indexes Columns**

Name	Type	References	Description
schemaname	name	<code>pg_namespace .nspname</code>	Name of schema containing table and index
tablename	name	<code>pg_class .relname</code>	Name of table the index is for
indexname	name	<code>pg_class .relname</code>	Name of index
tablespace	name	<code>pg_tablespace.spcname</code>	Name of tablespace containing index (null if default for database)
indexdef	text		Index definition (a reconstructed <code>CREATE INDEX</code> command)

## 52.73. pg\_locks

The view `pg_locks` provides access to information about the locks held by active processes within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant process. Thus, the same lockable object might appear many times, if multiple processes are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general

database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

**Table 52.74. `pg_locks` Columns**

Name	Type	References	Description
<code>locktype</code>	<code>text</code>		Type of the lockable object: <code>relation</code> , <code>extend</code> , <code>page</code> , <code>tuple</code> , <code>transactionid</code> , <code>virtualxid</code> , <code>object</code> , <code>userlock</code> , or <code>advisory</code>
<code>database</code>	<code>oid</code>	<code>pg_database .oid</code>	OID of the database in which the lock target exists, or zero if the target is a shared object, or null if the target is a transaction ID
<code>relation</code>	<code>oid</code>	<code>pg_class .oid</code>	OID of the relation targeted by the lock, or null if the target is not a relation or part of a relation
<code>page</code>	<code>integer</code>		Page number targeted by the lock within the relation, or null if the target is not a relation page or tuple
<code>tuple</code>	<code>smallint</code>		Tuple number targeted by the lock within the page, or null if the target is not a tuple
<code>virtualxid</code>	<code>text</code>		Virtual ID of the transaction targeted by the lock, or null if the target is not a virtual transaction ID
<code>transactionid</code>	<code>xid</code>		ID of the transaction targeted by the lock, or null if the target is not a transaction ID
<code>classid</code>	<code>oid</code>	<code>pg_class .oid</code>	OID of the system catalog containing the lock target, or null if the target is not a general database object
<code>objid</code>	<code>oid</code>	any OID column	OID of the lock target within its system catalog, or null if the target is not a general database object
<code>objsubid</code>	<code>smallint</code>		Column number targeted by the lock (the <code>classid</code> and <code>objid</code> refer to the table itself), or zero if the

Name	Type	References	Description
			target is some other general database object, or null if the target is not a general database object
virtualtransaction	text		Virtual ID of the transaction that is holding or awaiting this lock
pid	integer		Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction
mode	text		Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3)
granted	boolean		True if lock is held, false if lock is awaited
fastpath	boolean		True if lock was taken via fast path, false if taken via main lock table

`granted` is true in a row representing a lock held by the indicated process. False indicates that this process is currently waiting to acquire this lock, which implies that at least one other process is holding or waiting for a conflicting lock mode on the same lockable object. The waiting process will sleep until the other lock is released (or a deadlock situation is detected). A single process can be waiting to acquire at most one lock at a time.

Throughout running a transaction, a server process holds an exclusive lock on the transaction's virtual transaction ID. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on the transaction's permanent transaction ID until it ends. When a process finds it necessary to wait specifically for another transaction to end, it does so by attempting to acquire share lock on the other transaction's ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a process is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

Advisory locks can be acquired on keys consisting of either a single `bigint` value or two integer values. A `bigint` key is displayed with its high-order half in the `classid` column, its low-order half in the `objid` column, and `objsubid` equal to 1. The original `bigint` value can be reassembled with the expression `(classid::bigint << 32) | objid::bigint`. Integer keys are displayed with the first key in the `classid` column, the second key in the `objid` column, and `objsubid` equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the `database` column is meaningful for an advisory lock.

`pg_locks` provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its `relation` column can be joined against `pg_class.oid` to identify locked relations, this will only work correctly for relations in the current database (those for which the `database` column is either the current database's OID or zero).

The `pid` column can be joined to the `pid` column of the `pg_stat_activity` view to get more information on the session holding or awaiting each lock, for example

```
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
    ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the `virtualtransaction` column can be joined to the `transaction` column of the `pg_prepared_xacts` view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
    ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

While it is possible to obtain information about which processes block which other processes by joining `pg_locks` against itself, this is very difficult to get right in detail. Such a query would have to encode knowledge about which lock modes conflict with which others. Worse, the `pg_locks` view does not expose information about which processes are ahead of which others in lock wait queues, nor information about which processes are parallel workers running on behalf of which other client sessions. It is better to use the `pg_blocking_pids()` function (see Table 9.60) to identify which process(es) a waiting process is blocked behind.

The `pg_locks` view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and *fast-path* locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with `fastpath = true`) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.

## 52.74. `pg_matviews`

The view `pg_matviews` provides access to useful information about each materialized view in the database.

**Table 52.75. `pg_matviews` Columns**

Name	Type	References	Description
<code>schemaname</code>	name	<code>pg_namespace .nspname</code>	Name of schema containing materialized view
<code>matviewname</code>	name	<code>pg_class .relname</code>	Name of materialized view
<code>matviewowner</code>	name	<code>pg_authid .rolname</code>	Name of materialized view's owner
<code>tablespace</code>	name	<code>pg_tablespace .spcname</code>	Name of tablespace containing materialized view (null if default for database)

Name	Type	References	Description
hasindexes	boolean		True if materialized view has (or recently had) any indexes
ispopulated	boolean		True if materialized view is currently populated
definition	text		Materialized view definition (a reconstructed SELECT query)

## 52.75. pg\_policies

The view `pg_policies` provides access to useful information about each row-level security policy in the database.

**Table 52.76. pg\_policies Columns**

Name	Type	References	Description
schemaname	name	<code>pg_namespace .nspname</code>	Name of schema containing table policy is on
tablename	name	<code>pg_class .relname</code>	Name of table policy is on
policyname	name	<code>pg_policy .polname</code>	Name of policy
polpermissive	text		Is the policy permissive or restrictive?
roles	name[]		The roles to which this policy applies
cmd	text		The command type to which the policy is applied
qual	text		The expression added to the security barrier qualifications for queries that this policy applies to
with_check	text		The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table

## 52.76. pg\_prepared\_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See `PREPARE` for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the `DEALLOCATE` command).

**Table 52.77. pg\_prepared\_statements Columns**

Name	Type	Description
name	text	The identifier of the prepared statement

Name	Type	Description
statement	text	The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <code>PREPARE</code> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.
prepare_time	timestamptz	The time at which the prepared statement was created
parameter_types	regtype[]	The expected parameter types for the prepared statement in the form of an array of <code>regtype</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code> .
from_sql	boolean	<code>true</code> if the prepared statement was created via the <code>PREPARE SQL</code> command; <code>false</code> if the statement was prepared via the frontend/backend protocol

The `pg_prepared_statements` view is read only.

## 52.77. `pg_prepared_xacts`

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see `PREPARE TRANSACTION` for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

**Table 52.78. `pg_prepared_xacts` Columns**

Name	Type	References	Description
transaction	xid		Numeric transaction identifier of the prepared transaction
gid	text		Global transaction identifier that was assigned to the transaction
prepared	timestamp with time zone		Time at which the transaction was prepared for commit
owner	name	<code>pg_authid .rolname</code>	Name of the user that executed the transaction
database	name	<code>pg_database .datname</code>	Name of the database in which the transaction was executed

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a

consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

## 52.78. pg\_publication\_tables

The view `pg_publication_tables` provides information about the mapping between publications and the tables they contain. Unlike the underlying catalog `pg_publication_rel`, this view expands publications defined as `FOR ALL TABLES`, so for such publications there will be a row for each eligible table.

**Table 52.79. pg\_publication\_tables Columns**

Name	Type	References	Description
pubname	name	pg_publication.pubname	Name of publication
schemaname	name	pg_namespace .nspname	Name of schema containing table
tablename	name	pg_class .relname	Name of table

## 52.79. pg\_replication\_origin\_status

The `pg_replication_origin_status` view contains information about how far replay for a certain origin has progressed. For more on replication origins see Chapter 50.

**Table 52.80. pg\_replication\_origin\_status Columns**

Name	Type	References	Description
local_id	Oid	pg_replication_origin.roident	internal node identifier
external_id	text	pg_replication_origin.roname	external node identifier
remote_lsn	pg_lsn		The origin node's LSN up to which data has been replicated.
local_lsn	pg_lsn		This node's LSN at which <code>remote_lsn</code> has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.

## 52.80. pg\_replication\_slots

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see Section 27.2.6 and Chapter 49.

**Table 52.81. pg\_replication\_slots Columns**

Name	Type	References	Description
slot_name	name		A unique, cluster-wide identifier for the replication slot
plugin	name		The base name of the shared object containing the output plugin this

Name	Type	References	Description
			logical slot is using, or null for physical slots.
slot_type	text		The slot type - physical or logical
datoid	oid	pg_database .oid	The OID of the database this slot is associated with, or null. Only logical slots have an associated database.
database	text	pg_database .datname	The name of the database this slot is associated with, or null. Only logical slots have an associated database.
temporary	boolean		True if this is a temporary replication slot. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.
active	boolean		True if this slot is currently actively being used
active_pid	integer		The process ID of the session using this slot if the slot is currently actively being used. NULL if inactive.
xmin	xid		The oldest transaction that this slot needs the database to retain. VACUUM cannot remove tuples deleted by any later transaction.
catalog_xmin	xid		The oldest transaction affecting the system catalogs that this slot needs the database to retain. VACUUM cannot remove catalog tuples deleted by any later transaction.
restart_lsn	pg_lsn		The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won't be automatically removed during checkpoints.
confirmed_flush_lsn	pg_lsn		The address (LSN) up to which the logical slot's consumer has confirmed

Name	Type	References	Description
			receiving data. Data older than this is not available anymore. NULL for physical slots.

## 52.81. pg\_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

**Table 52.82. pg\_roles Columns**

Name	Type	References	Description
<code>rolname</code>	<code>name</code>		Role name
<code>rolsuper</code>	<code>bool</code>		Role has superuser privileges
<code>rolinherit</code>	<code>bool</code>		Role automatically inherits privileges of roles it is a member of
<code>rolcreaterole</code>	<code>bool</code>		Role can create more roles
<code>rolcreatedb</code>	<code>bool</code>		Role can create databases
<code>rolcanlogin</code>	<code>bool</code>		Role can log in. That is, this role can be given as the initial session authorization identifier
<code>rolreplication</code>	<code>bool</code>		Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.
<code>rolconlimit</code>	<code>int4</code>		For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.
<code>rolpassword</code>	<code>text</code>		Not the password (always reads as <code>*****</code> )
<code>rolvaliduntil</code>	<code>timestampz</code>		Password expiry time (only used for password authentication); null if no expiration
<code>rolbypassrls</code>	<code>bool</code>		Role bypasses every row level security policy, see Section 5.7 for more information.
<code>rolconfig</code>	<code>text[]</code>		Role-specific defaults for run-time configuration variables

Name	Type	References	Description
oid	oid	pg_authid .oid	ID of role

## 52.82. pg\_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

**Table 52.83. pg\_rules Columns**

Name	Type	References	Description
schemaname	name	pg_namespace .nspname	Name of schema containing table
tablename	name	pg_class .relname	Name of table the rule is for
rulename	name	pg_rewrite .rulename	Name of rule
definition	text		Rule definition (a reconstructed creation command)

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

## 52.83. pg\_seclabels

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

**Table 52.84. pg\_seclabels Columns**

Name	Type	References	Description
objoid	oid	any OID column	The OID of the object this security label pertains to
classoid	oid	pg_class .oid	The OID of the system catalog this object appears in
objsubid	int4		For a security label on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero.
objtype	text		The type of object to which this label applies, as text.
objnamespace	oid	pg_namespace .oid	The OID of the namespace for this object, if applicable; otherwise NULL.
objname	text		The name of the object to which this label applies, as text.

Name	Type	References	Description
provider	text	pg_seclabel .provider	The label provider associated with this label.
label	text	pg_seclabel .label	The security label applied to this object.

## 52.84. pg\_sequences

The view `pg_sequences` provides access to useful information about each sequence in the database.

**Table 52.85. pg\_sequences Columns**

Name	Type	References	Description
schemaname	name	pg_namespace .nspname	Name of schema containing sequence
sequencename	name	pg_class .relname	Name of sequence
sequenceowner	name	pg_authid .rolname	Name of sequence's owner
data_type	regtype	pg_type .oid	Data type of the sequence
start_value	bigint		Start value of the sequence
min_value	bigint		Minimum value of the sequence
max_value	bigint		Maximum value of the sequence
increment_by	bigint		Increment value of the sequence
cycle	boolean		Whether the sequence cycles
cache_size	bigint		Cache size of the sequence
last_value	bigint		The last sequence value written to disk. If caching is used, this value can be greater than the last value handed out from the sequence. Null if the sequence has not been read from yet. Also, if the current user does not have <code>USAGE</code> or <code>SELECT</code> privilege on the sequence, the value is null.

## 52.85. pg\_settings

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the `SHOW` and `SET` commands. It also provides access to some facts about each parameter that are not directly available from `SHOW`, such as minimum and maximum values.

**Table 52.86. pg\_settings Columns**

<b>Name</b>	<b>Type</b>	<b>Description</b>
name	text	Run-time configuration parameter name
setting	text	Current value of the parameter
unit	text	Implicit unit of the parameter
category	text	Logical group of the parameter
short_desc	text	A brief description of the parameter
extra_desc	text	Additional, more detailed, description of the parameter
context	text	Context required to set the parameter's value (see below)
vartype	text	Parameter type (bool, enum, integer, real, or string)
source	text	Source of the current parameter value
min_val	text	Minimum allowed value of the parameter (null for non-numeric values)
max_val	text	Maximum allowed value of the parameter (null for non-numeric values)
enumvals	text []	Allowed values of an enum parameter (null for non-enum values)
boot_val	text	Parameter value assumed at server startup if the parameter is not otherwise set
reset_val	text	Value that RESET would reset the parameter to in the current session
sourcefile	text	Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a user who is neither a superuser or a member of pg_read_all_settings ); helpful when using include directives in configuration files
sourceline	integer	Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a user who is neither a superuser or a member of pg_read_all_settings).
pending_restart	boolean	true if the value has been changed in the configuration file

Name	Type	Description
		but needs a restart; or <code>false</code> otherwise.

There are several possible values of `context`. In order of decreasing difficulty of changing the setting, they are:

#### internal

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

#### postmaster

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower `context` types can also be set at server start time.

#### sighup

Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the `SIGHUP` signal to its child processes so that they all pick up the new value.

#### superuser-backend

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via `libpq`'s `PGOPTIONS` environment variable), but only if the connecting user is a superuser. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

#### backend

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via `libpq`'s `PGOPTIONS` environment variable); any user can make such a change for their session. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a `SIGHUP` signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

#### superuser

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

#### user

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change their session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See Section 20.1 for more information about the various ways to change these parameters.

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once

the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

## 52.86. `pg_shadow`

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

**Table 52.87. `pg_shadow` Columns**

Name	Type	References	Description
<code>username</code>	<code>name</code>	<code>pg_authid .rolname</code>	User name
<code>usesysid</code>	<code>oid</code>	<code>pg_authid .oid</code>	ID of this user
<code>usecreatedb</code>	<code>bool</code>		User can create databases
<code>usesuper</code>	<code>bool</code>		User is a superuser
<code>userepl</code>	<code>bool</code>		User can initiate streaming replication and put the system in and out of backup mode.
<code>usebypassrsls</code>	<code>bool</code>		User bypasses every row level security policy, see Section 5.7 for more information.
<code>passwd</code>	<code>text</code>		Password (possibly encrypted); null if none. See <code>pg_authid</code> for details of how encrypted passwords are stored.
<code>valuntil</code>	<code>abstime</code>		Password expiry time (only used for password authentication)
<code>useconfig</code>	<code>text[]</code>		Session defaults for runtime configuration variables

## 52.87. `pg_stats`

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

**Table 52.88. `pg_stats` Columns**

Name	Type	References	Description
<code>schemaname</code>	<code>name</code>	<code>pg_namespace .nspname</code>	Name of schema containing table
<code>tablename</code>	<code>name</code>	<code>pg_class .relname</code>	Name of table

<b>Name</b>	<b>Type</b>	<b>References</b>	<b>Description</b>
attname	name	pg_attribute .attname	Name of the column described by this row
inherited	bool		If true, this row includes inheritance child columns, not just the values in the specified table
null_frac	real		Fraction of column entries that are null
avg_width	integer		Average width in bytes of column's entries
n_distinct	real		If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.
most_common_vals	anyarray		A list of the most common values in the column. (Null if no values seem to be more common than any others.)
most_common_freqs	real[]		A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when most_common_vals is.)
histogram_bounds	anyarray		A list of values that divide the column's values into groups of approximately equal population. The values in most_common_vals, if present, are omitted from this histogram calculation. (This column is null if the

Name	Type	References	Description
			column data type does not have a < operator or if the <code>most_common_vals</code> list accounts for the entire population.)
correlation	real		Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a < operator.)
most_common_elems	anyarray		A list of non-null element values most often appearing within values of the column. (Null for scalar types.)
most_common_elem_freqs	real[]		A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when <code>most_common_elems</code> is.)
elem_count_histogram	real[]		A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` runtime parameter.

## 52.88. pg\_tables

The view `pg_tables` provides access to useful information about each table in the database.

**Table 52.89. pg\_tables Columns**

Name	Type	References	Description
<code>schemaname</code>	<code>name</code>	<code>pg_namespace .nspname</code>	Name of schema containing table
<code>tablename</code>	<code>name</code>	<code>pg_class .relname</code>	Name of table
<code>tableowner</code>	<code>name</code>	<code>pg_authid .rolname</code>	Name of table's owner
<code>tablespace</code>	<code>name</code>	<code>pg_tablespace.spcname</code>	Name of tablespace containing table (null if default for database)
<code>hasindexes</code>	<code>boolean</code>	<code>pg_class .relhasindex</code>	True if table has (or recently had) any indexes
<code>hasrules</code>	<code>boolean</code>	<code>pg_class .relhasrules</code>	True if table has (or once had) rules
<code>hastriggers</code>	<code>boolean</code>	<code>pg_class.relhastriggers</code>	True if table has (or once had) triggers
<code>rowsecurity</code>	<code>boolean</code>	<code>pg_class.relrowsecurity</code>	True if row security is enabled on the table

## 52.89. pg\_timezone\_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the `timezone_abbreviations` runtime parameter is modified.

**Table 52.90. pg\_timezone\_abbrevs Columns**

Name	Type	Description
<code>abbrev</code>	<code>text</code>	Time zone abbreviation
<code>utc_offset</code>	<code>interval</code>	Offset from UTC (positive means east of Greenwich)
<code>is_dst</code>	<code>boolean</code>	True if this is a daylight-savings abbreviation

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.3 for more information). In such cases this view presents their current meaning.

## 52.90. pg\_timezone\_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, does not use UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

**Table 52.91. pg\_timezone\_names Columns**

Name	Type	Description
<code>name</code>	<code>text</code>	Time zone name

Name	Type	Description
abbrev	text	Time zone abbreviation
utc_offset	interval	Offset from UTC (positive means east of Greenwich)
is_dst	boolean	True if currently observing daylight savings

## 52.91. pg\_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

**Table 52.92. pg\_user Columns**

Name	Type	Description
username	name	User name
usesysid	oid	ID of this user
usecreatedb	bool	User can create databases
usesuper	bool	User is a superuser
userepl	bool	User can initiate streaming replication and put the system in and out of backup mode.
usebypassrls	bool	User bypasses every row level security policy, see Section 5.7 for more information.
passwd	text	Not the password (always reads as *****)
valuntil	abstime	Password expiry time (only used for password authentication)
useconfig	text []	Session defaults for run-time configuration variables

## 52.92. pg\_user\_mappings

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the options field if the user has no rights to use it.

**Table 52.93. pg\_user\_mappings Columns**

Name	Type	References	Description
umid	oid	<code>pg_user_mapping .oid</code>	OID of the user mapping
srvid	oid	<code>pg_foreign_server.oid</code>	The OID of the foreign server that contains this mapping
srvname	name	<code>pg_foreign_server.srvname</code>	Name of the foreign server
umuser	oid	<code>pg_authid .oid</code>	OID of the local role being mapped, 0 if the user mapping is public
username	name		Name of the local user to be mapped

Name	Type	References	Description
umoptions	text []		User mapping specific options, as “key-word=value” strings

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

## 52.93. pg\_views

The view `pg_views` provides access to useful information about each view in the database.

**Table 52.94. pg\_views Columns**

Name	Type	References	Description
schemaname	name	pg_namespace .nspname	Name of schema containing view
viewname	name	pg_class .relname	Name of view
viewowner	name	pg_authid .rolname	Name of view's owner
definition	text		View definition (a reconstructed <code>SELECT</code> query)

---

# Chapter 53. Frontend/Backend Protocol

uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use, and then the server follows that protocol if it is able.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

## 53.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as `NOTIFY`) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as `COPY`.

### 53.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communica-

tions failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

### 53.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: *prepared statements* and *portals*. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for *parameters*. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For `SELECT` statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don't handle non-`SELECT` statements.)

The overall execution cycle consists of a *parse* step, which creates a prepared statement from a textual query string; a *bind* step, which creates a portal given a prepared statement and values for any needed parameters; and an *execute* step that runs a portal's query. In the case of a query that returns rows (`SELECT`, `SHOW`, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

### 53.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different *formats*. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a *format code*. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

## 53.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 53.7.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, `COPY`, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

### 53.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as `pg_hba.conf`) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI, SSPI and SASL, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI, SSPI and SASL, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse), or sending AuthenticationOk.

The possible messages from the server in this phase are:

#### ErrorResponse

The connection attempt has been rejected. The server then immediately closes the connection.

#### AuthenticationOk

The authentication exchange is successfully completed.

#### AuthenticationKerberosV5

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.

#### AuthenticationCleartextPassword

The frontend must now send a PasswordMessage containing the password in clear-text form. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse.

#### AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

#### AuthenticationSCMCredential

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it's only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

#### AuthenticationGSS

The frontend must now initiate a GSSAPI negotiation. The frontend will send a GSSResponse message with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

#### AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a GSSResponse with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

#### AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or

SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another GSSResponse message. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

#### AuthenticationSASL

The frontend must now initiate a SASL negotiation, using one of the SASL mechanisms listed in the message. The frontend will send a SASLInitialResponse with the name of the selected mechanism, and the first part of the SASL data stream in response to this. If further messages are needed, the server will respond with AuthenticationSASLContinue. See Section 53.3 for details.

#### AuthenticationSASLContinue

This message contains challenge data from the previous step of SASL negotiation (AuthenticationSASL, or a previous AuthenticationSASLContinue). The frontend must respond with a SASLResponse message.

#### AuthenticationSASLFinal

SASL authentication has completed with additional mechanism-specific data for the client. The server will next send AuthenticationOk to indicate successful authentication, or an ErrorResponse to indicate failure. This message is sent only if the SASL mechanism specifies additional data to be sent from server to client at completion.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

#### BackendKeyData

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

#### ParameterStatus

This message informs the frontend about the current (initial) setting of backend parameters, such as client\_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 53.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

#### ReadyForQuery

Start-up is completed. The frontend can now issue commands.

#### ErrorResponse

Start-up failed. The connection is closed after sending this message.

#### NoticeResponse

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

### 53.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

#### CommandComplete

An SQL command completed normally.

#### CopyInResponse

The backend is ready to copy data from the frontend to a table; see Section 53.2.5.

#### CopyOutResponse

The backend is ready to copy data from a table to the frontend; see Section 53.2.5.

#### RowDescription

Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc query. The contents of this message describe the column layout of the rows. This will be followed by a `DataRow` message for each row being returned to the frontend.

#### DataRow

One of the set of rows returned by a `SELECT`, `FETCH`, etc query.

#### EmptyQueryResponse

An empty query string was recognized.

#### ErrorResponse

An error has occurred.

#### ReadyForQuery

Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (`CommandComplete` marks the end of processing one SQL command, not the whole string.) `ReadyForQuery` will always be sent, whether processing terminates successfully or with an error.

#### NoticeResponse

A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of `RowDescription`, zero or more `DataRow` messages, and then `CommandComplete`. `COPY` to or from the frontend invokes special protocol as described in Section 53.2.5. All other query types normally produce only a `CommandComplete` message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. `ReadyForQuery` is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is `EmptyQueryResponse` followed by `ReadyForQuery`.

In the event of an error, `ErrorResponse` is issued followed by `ReadyForQuery`. All further processing of the query string is aborted by `ErrorResponse` (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a `FETCH` from a cursor declared with the `BINARY` option. In that case, the retrieved values are in binary format. The format codes given in the `RowDescription` message tell which format is being used.

A frontend must be prepared to accept `ErrorResponse` and `NoticeResponse` messages whenever it is expecting any other type of message. See also Section 53.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

### 53.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a `Parse` message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either `ParseComplete` or `ErrorResponse`. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

#### Note

A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols ( $\$n$ ) used in the query string. Another special case is that a parameter's type can be specified as `void` (that is, the OID of the `void` pseudo-type). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1, $2, $3, $4)` could match a function with two IN and two OUT arguments, if `$3` and `$4` are specified as having type `void`.

#### Note

The query string contained in a `Parse` message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any `void` parameters in the Parse message, pass `NULL` values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either `BindComplete` or `ErrorResponse`.

### Note

The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The `BINARY` attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using `DECLARE CURSOR` and `FETCH`.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn't cause `ReadyForQuery` or `RowDescription` to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a `PortalSuspended` message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The `CommandComplete` message indicating completion of the source SQL command is not sent until the portal's execution is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these messages: `CommandComplete`, `EmptyQueryResponse` (if the portal was created from an empty query string), `ErrorResponse`, or `PortalSuspended`.

At completion of each series of extended-query messages, the frontend should issue a Sync message. This parameterless message causes the backend to close the current transaction if it's not inside a `BEGIN/COMMIT` transaction block (“close” meaning to commit if no error, or roll back if error). Then a `ReadyForQuery` response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues `ErrorResponse`, then reads and discards messages until a Sync is reached, then issues `ReadyForQuery`

and returns to normal message processing. (But note that no skipping occurs if an error is detected *while* processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

### Note

Sync does not cause a transaction block opened with `BEGIN` to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

### Tip

In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

### Note

The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

## 53.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database's `pg_proc` system catalog. The client must have execute permission for the function.

**Note**

The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a `FunctionCall` message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a `ReadyForQuery` response message. `ReadyForQuery` informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

**ErrorResponse**

An error has occurred.

**FunctionCallResponse**

The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)

**ReadyForQuery**

Processing of the function call is complete. `ReadyForQuery` will always be sent, whether processing terminates successfully or with an error.

**NoticeResponse**

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

### 53.2.5. COPY Operations

The `COPY` command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a `CopyInResponse` message to the frontend. The frontend should then send zero or more `CopyData` messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a `CopyDone` message (allowing successful termination) or a `CopyFail` message (which will cause the `COPY` SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either `CommandComplete` (if successful) or `ErrorResponse` (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a `CopyFail` message), the backend will issue an `ErrorResponse` message. If the `COPY` command was issued via an extended-query message, the backend will now discard frontend messages until a `Sync` message is received, then it will issue `ReadyForQuery` and return to normal processing. If the `COPY` command was issued in a simple Query message, the rest of that message is discarded and `ReadyForQuery` is issued. In either case, any subsequent `CopyData`, `CopyDone`, or `CopyFail` messages issued by the frontend will simply be dropped.

The backend will ignore `Flush` and `Sync` messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for `Flush` and `Sync` is for the convenience of client libraries that always send `Flush` or `Sync` after an `Execute` message, without checking whether the command to be executed is a `COPY FROM STDIN`.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a `COPY TO STDOUT` SQL statement. The backend sends a `CopyOutResponse` message to the frontend, followed by zero or more `CopyData` messages (always one per row), followed by `CopyDone`. The backend then reverts to the command-processing mode it was in before the `COPY` started, and sends `CommandComplete`. The frontend cannot abort the transfer (except by closing the connection or issuing a `Cancel` request), but it can discard unwanted `CopyData` and `CopyDone` messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an `ErrorResponse` message and revert to normal processing. The frontend should treat receipt of `ErrorResponse` as terminating the copy-out mode.

It is possible for `NoticeResponse` and `ParameterStatus` messages to be interspersed between `CopyData` messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 53.2.6). Otherwise, any message type other than `CopyData` or `CopyDone` may be treated as terminating copy-out mode.

There is another Copy-related mode called `copy-both`, which allows high-speed bulk data transfer to *and* from the server. `Copy-both` mode is initiated when a backend in `walsender` mode executes a `START_REPLICATION` statement. The backend sends a `CopyBothResponse` message to the frontend. Both the backend and the frontend may then send `CopyData` messages until either end sends a `CopyDone` message. After the client sends a `CopyDone` message, the connection goes from `copy-both` mode to `copy-out` mode, and the client may not send any more `CopyData` messages. Similarly, when the server sends a `CopyDone` message, the connection goes into `copy-in` mode, and the server may not send any more `CopyData` messages. After both sides have sent a `CopyDone` message, the copy mode is terminated, and the backend reverts to the command-processing mode. In the event of a backend-detected error during `copy-both` mode, the backend will issue an `ErrorResponse` message, discard frontend messages until a `Sync` message is received, and then issue `ReadyForQuery` and return to normal processing. The frontend should treat receipt of `ErrorResponse` as terminating the copy in both directions; no `CopyDone` should be sent in this case. See Section 53.4 for more information on the subprotocol transmitted over `copy-both` mode.

The `CopyInResponse`, `CopyOutResponse` and `CopyBothResponse` messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given `COPY` operation will use the same format, but the message design does not assume this.)

## 53.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend's command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for `NoticeResponse` messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a `NoticeResponse` indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display `NoticeResponse` messages, even when the connection is nominally idle.

`ParameterStatus` messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a `SET SQL` command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the `SIGHUP` signal to the server. Also, if a `SET` command is rolled back, an appropriate `ParameterStatus` message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which `ParameterStatus` will be generated: they are `server_version`, `server_encoding`, `client_encoding`, `application_name`, `is_superuser`, `session_authorization`, `DateStyle`, `IntervalStyle`, `TimeZone`, `integer_datetimes`, and `standard_conforming_strings`. (`server_encoding`, `TimeZone`, and `integer_datetimes` were not reported by releases before 8.0; `standard_conforming_strings` was not reported by releases before 8.1; `IntervalStyle` was

not reported by releases before 8.4; `application_name` was not reported by releases before 9.0.) Note that `server_version`, `server_encoding` and `integer_datetimes` are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore `ParameterStatus` for parameters that it does not understand or care about.

If a frontend issues a `LISTEN` command, then the backend will send a `NotificationResponse` message (not to be confused with `NoticeResponse`!) whenever a `NOTIFY` command is executed for the same channel name.

### Note

At present, `NotificationResponse` can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before `ReadyForQuery`. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept `NotificationResponse` at any point in the protocol.

## 53.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don't want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a `CancelRequest` message, rather than the `StartupMessage` message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A `CancelRequest` message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

## 53.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a `Terminate` message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn't want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-`SELECT` query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (`BEGIN ... COMMIT` sequence) then its results might be committed before the disconnection is recognized.

### 53.2.9. SSL Session Encryption

If was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting sessions with SSL, see Section 19.9.

To initiate an SSL-encrypted connection, the frontend initially sends an `SSLRequest` message rather than a `StartupMessage`. The server then responds with a single byte containing `S` or `N`, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after `S`, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual `StartupMessage`. In this case the `StartupMessage` and all subsequent data will be SSL-encrypted. To continue after `N`, send the usual `StartupMessage` and proceed without encryption.

The frontend should also be prepared to handle an `ErrorMessage` response to `SSLRequest` from the server. This would only occur if the server predates the addition of SSL support to . (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial `SSLRequest` can also be used in a connection that is being opened to send a `CancelRequest` message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

## 53.3. SASL Authentication

*SASL* is a framework for authentication in connection-oriented protocols. At the moment, implements only one SASL authentication mechanism, SCRAM-SHA-256, but more might be added in the future. The below steps illustrate how SASL authentication is performed in general, while the next subsection gives more details on SCRAM-SHA-256.

### SASL Authentication Message Flow

1. To begin a SASL authentication exchange, the server sends an `AuthenticationSASL` message. It includes a list of SASL authentication mechanisms that the server can accept, in the server's preferred order.
2. The client selects one of the supported mechanisms from the list, and sends a `SASLInitialResponse` message to the server. The message includes the name of the selected mechanism, and an optional Initial Client Response, if the selected mechanism uses that.
3. One or more server-challenge and client-response message will follow. Each server-challenge is sent in an `AuthenticationSASLContinue` message, followed by a response from client in an `SASLResponse` message. The particulars of the messages are mechanism specific.
4. Finally, when the authentication exchange is completed successfully, the server sends an `AuthenticationSASLFinal` message, followed immediately by an `AuthenticationOk` message. The Authentica-

tionSASLFinal contains additional server-to-client data, whose content is particular to the selected authentication mechanism. If the authentication mechanism doesn't use additional data that's sent at completion, the AuthenticationSASLFinal message is not sent.

On error, the server can abort the authentication at any stage, and send an ErrorMessage.

### 53.3.1. SCRAM-SHA-256 authentication

SCRAM-SHA-256 (called just SCRAM from now on) is the only implemented SASL mechanism, at the moment. It is described in detail in RFC 7677 and RFC 5802.

When SCRAM-SHA-256 is used in , the server will ignore the user name that the client sends in the client-first-message. The user name that was already sent in the startup message is used instead. supports multiple character encodings, while SCRAM dictates UTF-8 to be used for the user name, so it might be impossible to represent the user name in UTF-8.

The SCRAM specification dictates that the password is also in UTF-8, and is processed with the SASLprep algorithm. , however, does not require UTF-8 to be used for the password. When a user's password is set, it is processed with SASLprep as if it was in UTF-8, regardless of the actual encoding used. However, if it is not a legal UTF-8 byte sequence, or it contains UTF-8 byte sequences that are prohibited by the SASLprep algorithm, the raw password will be used without SASLprep processing, instead of throwing an error. This allows the password to be normalized when it is in UTF-8, but still allows a non-UTF-8 password to be used, and doesn't require the system to know which encoding the password is in.

Channel binding has not been implemented yet.

#### Example

1. The server sends an AuthenticationSASL message. It includes a list of SASL authentication mechanisms that the server can accept.
2. The client responds by sending a SASLInitialResponse message, which indicates the chosen mechanism, SCRAM-SHA-256. In the Initial Client response field, the message contains the SCRAM client-first-message.
3. Server sends an AuthenticationSASLContinue message, with a SCRAM server-first message as the content.
4. Client sends a SASLResponse message, with SCRAM client-final-message as the content.
5. Server sends an AuthenticationSASLFinal message, with the SCRAM server-final-message, followed immediately by an AuthenticationOk message.

## 53.4. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the replication parameter in the startup message. A Boolean value of true tells the backend to go into walsender mode, wherein a small set of replication commands can be issued instead of SQL statements. Only the simple query protocol can be used in walsender mode. Replication commands are logged in the server log when log\_replication\_commands is enabled. Passing database as the value instructs walsender to connect to the database specified in the dbname parameter, which will allow the connection to be used for logical replication from that database.

For the purpose of testing replication commands, you can make a replication connection via psql or any other libpq-using tool with a connection string including the replication option, e.g.:

```
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"
```

However, it is often more useful to use pg\_receivewal (for physical replication) or pg\_recvlogical (for logical replication).

The commands accepted in walsender mode are:

## IDENTIFY\_SYSTEM

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

`systemid` (text)

The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

`timeline` (int4)

Current timeline ID. Also useful to check that the standby is consistent with the master.

`xlogpos` (text)

Current WAL flush location. Useful to get a known location in the write-ahead log where streaming can start.

`dbname` (text)

Database connected to or null.

SHOW *name*

Requests the server to send the current setting of a run-time parameter. This is similar to the SQL command SHOW.

*name*

The name of a run-time parameter. Available parameters are documented in Chapter 20.

TIMELINE\_HISTORY *tli*

Requests the server to send over the timeline history file for timeline *tli*. Server replies with a result set of a single row, containing two fields:

`filename` (text)

File name of the timeline history file, e.g., 00000002.history.

`content` (bytea)

Contents of the timeline history file.

CREATE\_REPLICATION\_SLOT *slot\_name* [ TEMPORARY ] { PHYSICAL [ RESERVE\_WAL ] | LOGICAL *output\_plugin* [ EXPORT\_SNAPSHOT | NOEXPORT\_SNAPSHOT | USE\_SNAPSHOT ] }

Create a physical or logical replication slot. See Section 27.2.6 for more about replication slots.

*slot\_name*

The name of the slot to create. Must be a valid replication slot name (see Section 27.2.6.1).

*output\_plugin*

The name of the output plugin used for logical decoding (see Section 49.6).

## TEMPORARY

Specify that this replication slot is a temporary one. Temporary slots are not saved to disk and are automatically dropped on error or when the session has finished.

## RESERVE\_WAL

Specify that this physical replication slot reserves WAL immediately. Otherwise, WAL is only reserved upon connection from a streaming replication client.

EXPORT\_SNAPSHOT  
 NOEXPORT\_SNAPSHOT  
 USE\_SNAPSHOT

Decides what to do with the snapshot created during logical slot initialization. `EXPORT_SNAPSHOT`, which is the default, will export the snapshot for use in other sessions. This option can't be used inside a transaction. `USE_SNAPSHOT` will use the snapshot for the current transaction executing the command. This option must be used in a transaction, and `CREATE_REPLICATION_SLOT` must be the first command run in that transaction. Finally, `NOEXPORT_SNAPSHOT` will just use the snapshot for logical decoding as normal but won't do anything else with it.

In response to this command, the server will send a one-row result set containing the following fields:

`slot_name` (text)

The name of the newly-created replication slot.

`consistent_point` (text)

The WAL location at which the slot became consistent. This is the earliest location from which streaming can start on this replication slot.

`snapshot_name` (text)

The identifier of the snapshot exported by the command. The snapshot is valid until a new command is executed on this connection or the replication connection is closed. Null if the created slot is physical.

`output_plugin` (text)

The name of the output plugin used by the newly-created replication slot. Null if the created slot is physical.

`START_REPLICATION [ SLOT slot_name ] [ PHYSICAL ] XXX/XXX [ TIMELINE tli ]`

Instructs server to start streaming WAL, starting at WAL location `XXX/XXX`. If `TIMELINE` option is specified, streaming starts on timeline `tli`; otherwise, the server's current timeline is selected. The server can reply with an error, for example if the requested section of WAL has already been recycled. On success, server responds with a `CopyBothResponse` message, and then starts to stream WAL to the frontend.

If a slot's name is provided via `slot_name`, it will be updated as replication progresses so that the server knows which WAL segments, and if `hot_standby_feedback` is on which transactions, are still needed by the standby.

If the client requests a timeline that's not the latest but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested start point up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with `CommandComplete` without entering `COPY` mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the `COPY` mode. When the client acknowledges this by also exiting `COPY` mode, the server sends a result set with one row and two columns, indicating the next timeline in this server's history. The first column is the next timeline's ID (type `int8`), and the second column is the WAL location where the switch happened (type `text`). Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends `CommandComplete` message, and is ready to accept a new command.

WAL data is sent as a series of `CopyData` messages. (This allows other information to be intermixed; in particular the server can send an `ErrorResponse` message if it encounters a failure after beginning to stream.) The payload of each `CopyData` message from server to the client contains a message of one of the following formats:

**XLogData (B)**

Byte1('w')

Identifies the message as WAL data.

Int64

The starting point of the WAL data in this message.

Int64

The current end of WAL on the server.

Int64

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte<sub>n</sub>

A section of the WAL data stream.

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.

**Primary keepalive message (B)**

Byte1('k')

Identifies the message as a sender keepalive.

Int64

The current end of WAL on the server.

Int64

The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

**Standby status update (F)**

Byte1('r')

Identifies the message as a receiver status update.

Int64

The location of the last WAL byte + 1 received and written to disk in the standby.

Int64

The location of the last WAL byte + 1 flushed to disk in the standby.

Int64

The location of the last WAL byte + 1 applied in the standby.

Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1

If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

Hot Standby feedback message (F)

Byte1('h')

Identifies the message as a Hot Standby feedback message.

Int64

The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Int32

The standby's current global xmin, excluding the catalog xmin from any replication slots. If both this value and the following catalog xmin are 0 this is treated as a notification that Hot Standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.

Int32

The epoch of the global xmin xid on the standby.

Int32

The lowest catalog xmin of any replication slots on the standby. Set to 0 if no catalog xmin exists on the standby or if hot standby feedback is being disabled.

Int32

The epoch of the catalog xmin xid on the standby.

`START_REPLICATION SLOT slot_name LOGICAL XXX/XXX [ ( option_name [ option_value ] [, ...] ) ]`

Instructs server to start streaming WAL for logical replication, starting at WAL location `XXX/XXX`. The server can reply with an error, for example if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

The messages inside the CopyBothResponse messages are of the same format documented for `START_REPLICATION ... PHYSICAL`.

The output plugin associated with the selected slot is used to process the output for streaming.

`SLOT slot_name`

The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with `CREATE_REPLICATION_SLOT` in LOGICAL mode.

`XXX/XXX`

The WAL location to begin streaming at.

`option_name`

The name of an option passed to the slot's logical decoding plugin.

`option_value`

Optional value, in the form of a string constant, associated with the specified option.

`DROP_REPLICATION_SLOT slot_name [ WAIT ]`

Drops a replication slot, freeing any reserved server-side resources. If the slot is a logical slot that was created in a database other than the database the walsender is connected to, this command fails.

*slot\_name*

The name of the slot to drop.

`WAIT`

This option causes the command to wait if the slot is active until it becomes inactive, instead of the default behavior of raising an error.

`BASE_BACKUP [ LABEL 'label' ] [ PROGRESS ] [ FAST ] [ WAL ] [ NOWAIT ] [ MAX_RATE rate ] [ TABLESPACE_MAP ]`

Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

`LABEL 'label'`

Sets the label of the backup. If none is specified, a backup label of `base backup` will be used. The quoting rules for the label are the same as a standard SQL string with `standard_conforming_strings` turned on.

`PROGRESS`

Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and might as such have a negative impact on the performance. In particular, it might take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and might both grow and shrink between the time of approximation and the sending of the actual files.

`FAST`

Request a fast checkpoint.

`WAL`

Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the `pg_wal` directory of the base directory tar file.

`NOWAIT`

By default, the backup will wait until the last required WAL segment has been archived, or emit a warning if log archiving is not enabled. Specifying `NOWAIT` disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

`MAX_RATE rate`

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

`TABLESPACE_MAP`

Include information about symbolic links present in the directory `pg_tblspc` in a file named `tablespace_map`. The tablespace map file includes each symbolic link name as it exists in the directory `pg_tblspc/` and the full path of that symbolic link.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

`spcoid (oid)`

The OID of the tablespace, or null if it's the base directory.

`spcllocation (text)`

The full path of the tablespace directory, or null if it's the base directory.

`size (int8)`

The approximate size of the tablespace, if progress report has been requested; otherwise it's null.

After the second regular result set, one or more CopyResponse results will be sent, one for the main data directory and one for each additional tablespace other than `pg_default` and `pg_global`. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of zeroes specified in the standard are omitted. After the tar data is complete, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are files or other files added to the same directory. The only excluded files are:

- `postmaster.pid`
- `postmaster.opts`
- Various temporary files and directories created during the operation of the server, such as any file or directory beginning with `pgsql_tmp`.
- `pg_wal`, including subdirectories. If the backup is run with WAL files included, a synthesized version of `pg_wal` will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- `pg_dynshmem`, `pg_notify`, `pg_replslot`, `pg_serial`, `pg_snapshots`, `pg_stat_tmp`, and `pg_subtrans` are copied as empty directories (even if they are symbolic links).
- Files other than regular files and directories, such as symbolic links (other than for the directories listed above) and special device files, are skipped. (Symbolic links in `pg_tblspc` are maintained.)

Owner, group, and file mode are set if the underlying file system on the server supports it.

## 53.5. Logical Streaming Replication Protocol

This section describes the logical replication protocol, which is the message flow started by the `START_REPLICATION SLOT slot_name LOGICAL` replication command.

The logical streaming replication protocol builds on the primitives of the physical streaming replication protocol.

### 53.5.1. Logical Streaming Replication Parameters

The logical replication `START_REPLICATION` command accepts following parameters:

`proto_version`

Protocol version. Currently only version 1 is supported.

publication\_names

Comma separated list of publication names for which to subscribe (receive changes). The individual publication names are treated as standard objects names and can be quoted the same as needed.

## 53.5.2. Logical Replication Protocol Messages

The individual protocol messages are discussed in the following subsections. Individual messages are described in Section 53.9.

All top-level protocol messages begin with a message type byte. While represented in code as a character, this is a signed byte with no associated encoding.

Since the streaming replication protocol supplies a message length there is no need for top-level protocol messages to embed a length in their header.

## 53.5.3. Logical Replication Protocol Message Flow

With the exception of the `START_REPLICATION` command and the replay progress messages, all information flows only from the backend to the frontend.

The logical replication protocol sends individual transactions one by one. This means that all messages between a pair of Begin and Commit messages belong to the same transaction.

Every sent transaction contains zero or more DML messages (Insert, Update, Delete). In case of a cascaded setup it can also contain Origin messages. The origin message indicated that the transaction originated on different replication node. Since a replication node in the scope of logical replication protocol can be pretty much anything, the only identifier is the origin name. It's downstream's responsibility to handle this as needed (if needed). The Origin message is always sent before any DML messages in the transaction.

Every DML message contains an arbitrary relation ID, which can be mapped to an ID in the Relation messages. The Relation messages describe the schema of the given relation. The Relation message is sent for a given relation either because it is the first time we send a DML message for given relation in the current session or because the relation definition has changed since the last Relation message was sent for it. The protocol assumes that the client is capable of caching the metadata for as many relations as needed.

## 53.6. Message Data Types

This section describes the base data types used in messages.

`Int $n$ ( $i$ )`

An  $n$ -bit integer in network byte order (most significant byte first). If  $i$  is specified it is the exact value that will appear, otherwise the value is variable. Eg. `Int16`, `Int32(42)`.

`Int $n$ [ $k$ ]`

An array of  $k$   $n$ -bit integers, each in network byte order. The array length  $k$  is always determined by an earlier field in the message. Eg. `Int16[M]`.

`String( $s$ )`

A null-terminated string (C-style string). There is no specific length limitation on strings. If  $s$  is specified it is the exact value that will appear, otherwise the value is variable. Eg. `String`, `String("user")`.

### Note

*There is no predefined limit on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that*

fits in memory can be accepted. If that's not feasible, read the full string and discard trailing characters that don't fit into your fixed-size buffer.

Byte $n(c)$

Exactly  $n$  bytes. If the field width  $n$  is not a constant, it is always determinable from an earlier field in the message. If  $c$  is specified it is the exact value. Eg. Byte2, Byte1('\n').

## 53.7. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

AuthenticationOk (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(0)

Specifies that the authentication was successful.

AuthenticationKerberosV5 (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(2)

Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(3)

Specifies that a clear-text password is required.

AuthenticationMD5Password (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(12)

Length of message contents in bytes, including self.

Int32(5)

Specifies that an MD5-encrypted password is required.

Byte4

The salt to use when encrypting the password.

AuthenticationSCMCredential (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(6)

Specifies that an SCM credentials message is required.

AuthenticationGSS (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(7)

Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(9)

Specifies that SSPI authentication is required.

AuthenticationGSSContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte<sub>n</sub>

GSSAPI or SSPI authentication data.

AuthenticationSASL (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(10)

Specifies that SASL authentication is required.

The message body is a list of SASL authentication mechanisms, in the server's order of preference. A zero byte is required as terminator after the last authentication mechanism name. For each mechanism, there is the following:

String

Name of a SASL authentication mechanism.

AuthenticationSASLContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(11)

Specifies that this message contains a SASL challenge.

Byte<sub>n</sub>

SASL data, specific to the SASL mechanism being used.

AuthenticationSASLFinal (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(12)

Specifies that SASL authentication has completed.

Byte<sub>n</sub>

SASL outcome "additional data", specific to the SASL mechanism being used.

BackendKeyData (B)

Byte1('K')

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32(12)

Length of message contents in bytes, including self.

Int32

The process ID of this backend.

Int32

The secret key of this backend.

## Bind (F)

Byte1('B')

Identifies the message as a Bind command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination portal (an empty string selects the unnamed portal).

String

The name of the source prepared statement (an empty string selects the unnamed prepared statement).

Int16

The number of parameter format codes that follow (denoted  $c$  below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

Int16[ $c$ ]

The parameter format codes. Each must presently be zero (text) or one (binary).

Int16

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte $n$ 

The value of the parameter, in the format indicated by the associated format code.  $n$  is the above length.

After the last parameter, the following fields appear:

Int16

The number of result-column format codes that follow (denoted  $R$  below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

Int16[ $R$ ]

The result-column format codes. Each must presently be zero (text) or one (binary).

## BindComplete (B)

Byte1('2')

Identifies the message as a Bind-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

## CancelRequest (F)

Int32(16)

Length of message contents in bytes, including self.

Int32(80877102)

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32

The process ID of the target backend.

Int32

The secret key for the target backend.

## Close (F)

Byte1('C')

Identifies the message as a Close command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to close a prepared statement; or 'P' to close a portal.

String

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

## CloseComplete (B)

Byte1('3')

Identifies the message as a Close-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

## CommandComplete (B)

Byte1('C')

Identifies the message as a command-completed response.

Int32

Length of message contents in bytes, including self.

String

The command tag. This is usually a single word that identifies which SQL command was completed.

For an INSERT command, the tag is INSERT *oid rows*, where *rows* is the number of rows inserted. *oid* is the object ID of the inserted row if *rows* is 1 and the target table has OIDs; otherwise *oid* is 0.

For a DELETE command, the tag is DELETE *rows* where *rows* is the number of rows deleted.

For an UPDATE command, the tag is UPDATE *rows* where *rows* is the number of rows updated.

For a `SELECT` or `CREATE TABLE AS` command, the tag is `SELECT rows` where `rows` is the number of rows retrieved.

For a `MOVE` command, the tag is `MOVE rows` where `rows` is the number of rows the cursor's position has been changed by.

For a `FETCH` command, the tag is `FETCH rows` where `rows` is the number of rows that have been retrieved from the cursor.

For a `COPY` command, the tag is `COPY rows` where `rows` is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

#### CopyData (F & B)

Byte1('d')

Identifies the message as `COPY` data.

Int32

Length of message contents in bytes, including self.

Byte<sub>*n*</sub>

Data that forms part of a `COPY` data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

#### CopyDone (F & B)

Byte1('c')

Identifies the message as a `COPY`-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

#### CopyFail (F)

Byte1('f')

Identifies the message as a `COPY`-failure indicator.

Int32

Length of message contents in bytes, including self.

String

An error message to report as the cause of failure.

#### CopyInResponse (B)

Byte1('G')

Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a `CopyFail` message).

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall `COPY` format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to `DataRow` format). See `COPY` for more information.

Int16

The number of columns in the data to be copied (denoted  $N$  below).

Int16[ $N$ ]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1('H')

Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted  $N$  below).

Int16[ $N$ ]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyBothResponse (B)

Byte1('W')

Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted  $N$  below).

Int16[ $N$ ]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

DataRow (B)

Byte1('D')

Identifies the message as a data row.

Int32

Length of message contents in bytes, including self.

**Int16**

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

**Int32**

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

**Byte<sub>n</sub>**

The value of the column, in the format indicated by the associated format code. *n* is the above length.

**Describe (F)****Byte1('D')**

Identifies the message as a Describe command.

**Int32**

Length of message contents in bytes, including self.

**Byte1**

'S' to describe a prepared statement; or 'P' to describe a portal.

**String**

The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

**EmptyQueryResponse (B)****Byte1('I')**

Identifies the message as a response to an empty query string. (This substitutes for Command-Complete.)

**Int32(4)**

Length of message contents in bytes, including self.

**ErrorResponse (B)****Byte1('E')**

Identifies the message as an error.

**Int32**

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

**Byte1**

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 53.8. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

**String**

The field value.

## Execute (F)

Byte1('E')

Identifies the message as an Execute command.

Int32

Length of message contents in bytes, including self.

String

The name of the portal to execute (an empty string selects the unnamed portal).

Int32

Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes "no limit".

## Flush (F)

Byte1('H')

Identifies the message as a Flush command.

Int32(4)

Length of message contents in bytes, including self.

## FunctionCall (F)

Byte1('F')

Identifies the message as a function call.

Int32

Length of message contents in bytes, including self.

Int32

Specifies the object ID of the function to call.

Int16

The number of argument format codes that follow (denoted *c* below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[*c*]

The argument format codes. Each must presently be zero (text) or one (binary).

Int16

Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32

The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte<sub>*n*</sub>

The value of the argument, in the format indicated by the associated format code. *n* is the above length.

After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)

Byte1('V')

Identifies the message as a function call result.

Int32

Length of message contents in bytes, including self.

Int32

The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte<sub>*n*</sub>

The value of the function result, in the format indicated by the associated format code. *n* is the above length.

GSSResponse (F)

Byte1('p')

Identifies the message as a GSSAPI or SSPI response. Note that this is also used for SASL and password response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

Byte<sub>*n*</sub>

GSSAPI/SSPI specific message data.

NoData (B)

Byte1('n')

Identifies the message as a no-data indicator.

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 53.8. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

NotificationResponse (B)

Byte1('A')

Identifies the message as a notification response.

Int32

Length of message contents in bytes, including self.

Int32

The process ID of the notifying backend process.

String

The name of the channel that the notify has been raised on.

String

The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1('t')

Identifies the message as a parameter description.

Int32

Length of message contents in bytes, including self.

Int16

The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')

Identifies the message as a run-time parameter status report.

Int32

Length of message contents in bytes, including self.

String

The name of the run-time parameter being reported.

String

The current value of the parameter.

Parse (F)

Byte1('P')

Identifies the message as a Parse command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String

The query string to be parsed.

Int16

The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1('1')

Identifies the message as a Parse-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')

Identifies the message as a password response. Note that this is also used for GSSAPI, SSPI and SASL response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

String

The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')

Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message's row-count limit was reached.

Int32(4)

Length of message contents in bytes, including self.

Query (F)

Byte1('Q')

Identifies the message as a simple query.

Int32

Length of message contents in bytes, including self.

**String**

The query string itself.

**ReadyForQuery (B)****Byte1('Z')**

Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.

**Int32(5)**

Length of message contents in bytes, including self.

**Byte1**

Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

**RowDescription (B)****Byte1('T')**

Identifies the message as a row description.

**Int32**

Length of message contents in bytes, including self.

**Int16**

Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

**String**

The field name.

**Int32**

If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

**Int16**

If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

**Int32**

The object ID of the field's data type.

**Int16**

The data type size (see `pg_type.typelen`). Note that negative values denote variable-width types.

**Int32**

The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

**Int16**

The format code being used for the field. Currently will be zero (text) or one (binary). In a Row-Description returned from the statement variant of Describe, the format code is not yet known and will always be zero.

## SASLInitialResponse (F)

Byte1('p')

Identifies the message as an initial SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type is deduced from the context.

Int32

Length of message contents in bytes, including self.

String

Name of the SASL authentication mechanism that the client selected.

Int32

Length of SASL mechanism specific "Initial Client Response" that follows, or -1 if there is no Initial Response.

Byte<sub>n</sub>

SASL mechanism specific "Initial Response".

## SASLResponse (F)

Byte1('p')

Identifies the message as a SASL response. Note that this is also used for GSSAPI, SSPI and password response messages. The exact message type can be deduced from the context.

Int32

Length of message contents in bytes, including self.

Byte<sub>n</sub>

SASL mechanism specific message data.

## SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

## StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. `user` is required, others are optional. Each parameter is specified as:

String

The parameter name. Currently recognized names are:

user

The database user name to connect as. Required; there is no default.

database

The database to connect to. Defaults to the user name.

options

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (\); write \\ to represent a literal backslash.

replication

Used to connect in streaming replication mode, where a small set of replication commands can be issued instead of SQL statements. Value can be `true`, `false`, or `database`, and the default is `false`. See Section 53.4 for details.

In addition to the above, any run-time parameter that can be set at backend start time might be listed. Such settings will be applied during backend start (after parsing the command-line arguments if any). The values will act as session defaults.

String

The parameter value.

Sync (F)

Byte1('S')

Identifies the message as a Sync command.

Int32(4)

Length of message contents in bytes, including self.

Terminate (F)

Byte1('X')

Identifies the message as a termination.

Int32(4)

Length of message contents in bytes, including self.

## 53.8. Error and Notice Message Fields

This section describes the fields that can appear in `ErrorResponse` and `NoticeResponse` messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

S

**Severity:** the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message), or a localized translation of one of these. Always present.

V

**Severity:** the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message). This is identical to the `S` field except that the contents are never localized. This is present only in messages generated by versions 9.6 and later.

C

**Code:** the `SQLSTATE` code for the error (see Appendix A). Not localizable. Always present.

M

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

D

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

P

Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

q

Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

W

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

s

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

t

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table's schema.)

c

Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

d

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type's schema.)

n

Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren't created with constraint syntax.)

F

File: the file name of the source-code location where the error was reported.

L

Line: the line number of the source-code location where the error was reported.

R

Routine: the name of the source-code routine reporting the error.

### Note

The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see Appendix A. Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

## 53.9. Logical Replication Message Formats

This section describes the detailed format of each logical replication message. These messages are returned either by the replication slot SQL interface or are sent by a walsender. In case of a walsender they are encapsulated inside the replication protocol WAL messages as described in Section 53.4 and generally obey same message flow as physical replication.

Begin

Byte1('B')

Identifies the message as a begin message.

Int64

The final LSN of the transaction.

Int64

Commit timestamp of the transaction. The value is in number of microseconds since epoch (2000-01-01).

Int32

Xid of the transaction.

Commit

Byte1('C')

Identifies the message as a commit message.

Int8

Flags; currently unused (must be 0).

Int64

The LSN of the commit.

Int64

The end LSN of the transaction.

Int64

Commit timestamp of the transaction. The value is in number of microseconds since epoch (2000-01-01).

Origin

Byte1('O')

Identifies the message as an origin message.

Int64

The LSN of the commit on the origin server.

String

Name of the origin.

Note that there can be multiple Origin messages inside a single transaction.

Relation

Byte1('R')

Identifies the message as a relation message.

Int32

ID of the relation.

String

Namespace (empty string for `pg_catalog`).

String

Relation name.

Int8

Replica identity setting for the relation (same as `relreplident` in `pg_class`).

Int16

Number of columns.

Next, the following message part appears for each column:

Int8

Flags for the column. Currently can be either 0 for no flags or 1 which marks the column as part of the key.

String

Name of the column.

Int32

ID of the column's data type.

Int32

Type modifier of the column (`atttypmod`).

Type

Byte1('Y')

Identifies the message as a type message.

Int32

ID of the data type.

String

Namespace (empty string for `pg_catalog`).

String

Name of the data type.

Insert

Byte1('I')

Identifies the message as an insert message.

Int32

ID of the relation corresponding to the ID in the relation message.

Byte1('N')

Identifies the following TupleData message as a new tuple.

TupleData

TupleData message part representing the contents of new tuple.

Update

Byte1('U')

Identifies the message as an update message.

Int32

ID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is optional and is only present if the update changed data in any of the column(s) that are part of the REPLICA IDENTITY index.

Byte1('O')

Identifies the following TupleData submessage as an old tuple. This field is optional and is only present if table in which the update happened has REPLICA IDENTITY set to FULL.

TupleData

TupleData message part representing the contents of the old tuple or primary key. Only present if the previous 'O' or 'K' part is present.

Byte1('N')

Identifies the following TupleData message as a new tuple.

TupleData

TupleData message part representing the contents of a new tuple.

The Update message may contain either a 'K' message part or an 'O' message part or neither of them, but never both of them.

Delete

Byte1('D')

Identifies the message as a delete message.

Int32

ID of the relation corresponding to the ID in the relation message.

Byte1('K')

Identifies the following TupleData submessage as a key. This field is present if the table in which the delete has happened uses an index as REPLICA IDENTITY.

Byte1('O')

Identifies the following TupleData message as a old tuple. This field is is present if the table in which the delete has happened has REPLICA IDENTITY set to FULL.

TupleData

TupleData message part representing the contents of the old tuple or primary key, depending on the previous field.

The Delete message may contain either a 'K' message part or an 'O' message part, but never both of them.

The following message parts are shared by the above messages.

TupleData

Int16

Number of columns.

Next, one of the following submessages appears for each column:

Byte1('n')

Identifies the data as NULL value.

Or

Byte1('u')

Identifies unchanged TOASTed value (the actual value is not sent).

Or

Byte1('t')

Identifies the data as text formatted value.

Int32

Length of the column value.

Byte<sub>*n*</sub>

The value of the column, in text format. (A future release might support additional formats.) *n* is the above length.

## 53.10. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the `options` field, but given the limited width of `options` and the lack of any way to quote whitespace in the values, it wasn't a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that PasswordMessage now has a type byte.

ErrorResponse and NoticeResponse ('E' and 'N') messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The ReadyForQuery ('Z') message includes a transaction status indicator.

The distinction between BinaryRow and DataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server's internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special “\.” last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during COPY IN, but its use is deprecated and will eventually be removed.) Binary COPY is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus ('S') messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription ('T') message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse ('P') message is no longer generated by the backend.

The NotificationResponse ('A') message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse ('I') message used to include an empty string parameter; this has been removed.

---

# Chapter 54. Coding Conventions

## 54.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc) follow BSD conventions. In particular, curly braces for the controlled blocks of `if`, `while`, `switch`, etc go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn't mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

Do not use C++ style comments (`//` comments). Strict ANSI C compilers do not accept them. For the same reason, do not use C++ extensions such as declaring new variables mid-block.

The preferred style for multi-line comment blocks is

```
/*
 * comment text begins here
 * and continues here
 */
```

Note that comment blocks that begin in column 1 will be preserved as-is by `pgindent`, but it will re-flow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

```
/*-----
 * comment text begins here
 * and continues here
 *-----
 */
```

While submitted patches do not absolutely have to follow these formatting rules, it's a good idea to do so. Your code will get run through `pgindent` before the next release, so there's no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is "make the new code look like the existing code around it".

The `src/tools` directory contains sample settings files that can be used with the `emacs`, `xemacs` or `vim` editors to help ensure that they format code according to these conventions.

The text browsing tools `more` and `less` can be invoked as:

```
more -x4
less -x4
```

to make them show tabs appropriately.

## 54.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using `ereport`, or its older cousin `elog`. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from `DEBUG` to `PANIC`) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec's `SQLSTATE` conventions. `ereport` itself is just a shell function, that exists mainly for the syntactic convenience of making message generation look like a function call in the C source code. The only parameter accepted directly by `ereport` is the severity level. The primary

message text and any optional message elements are generated by calling auxiliary functions, such as `errmsg`, within the `ereport` call.

A typical call to `ereport` might look like this:

```
ereport (ERROR,
        (errcode(ERRCODE_DIVISION_BY_ZERO),
         errmsg("division by zero")));
```

This specifies error severity level `ERROR` (a run-of-the-mill error). The `errcode` call specifies the SQLSTATE error code using a macro defined in `src/include/utils/errcodes.h`. The `errmsg` call provides the primary message text. Notice the extra set of parentheses surrounding the auxiliary function calls — these are annoying but syntactically necessary.

Here is a more complex example:

```
ereport (ERROR,
        (errcode(ERRCODE_AMBIGUOUS_FUNCTION),
         errmsg("function %s is not unique",
              func_signature_string(funcname, nargs,
                                   NIL, actual_arg_types)),
         errhint("Unable to choose a best candidate function. "
                "You might need to add explicit typecasts.)));
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided.

If the severity level is `ERROR` or higher, `ereport` aborts the execution of the user-defined function and does not return to the caller. If the severity level is lower than `ERROR`, `ereport` returns normally.

The available auxiliary routines for `ereport` are:

- `errcode(sqlerrcode)` specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to `ERRCODE_INTERNAL_ERROR` when the error severity level is `ERROR` or higher, `ERRCODE_WARNING` when the error level is `WARNING`, otherwise (for `NOTICE` and below) `ERRCODE_SUCCESSFUL_COMPLETION`. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode()` call.
- `errmsg(const char *msg, ...)` specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by `sprintf`-style format codes. In addition to the standard format codes accepted by `sprintf`, the format code `%m` can be used to insert the error message returned by `strerror` for the current value of `errno`.<sup>1</sup> `%m` does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.
- `errmsg_internal(const char *msg, ...)` is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.
- `errmsg_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errmsg`, but with support for various plural forms of the message. `fmt_singular` is the English singular format, `fmt_plural` is the English plural format, `n` is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 55.2.2.
- `errdetail(const char *msg, ...)` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.
- `errdetail_internal(const char *msg, ...)` is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This

<sup>1</sup> That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`'s parameter list; accordingly, do not do so.

should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.

- `errdetail_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail`, but with support for various plural forms of the message. For more information see Section 55.2.2.
- `errdetail_log(const char *msg, ...)` is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.
- `errdetail_log_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 55.2.2.
- `errhint(const char *msg, ...)` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.
- `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.
- `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.
- `errtable(Relation rel)` specifies a relation whose name and schema name should be included as auxiliary fields in the error report.
- `errtablecol(Relation rel, int attnum)` specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.
- `errtableconstraint(Relation rel, const char *conname)` specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated `pg_constraint` entry. Be careful to pass the underlying heap relation, not the index itself, as `rel`.
- `errdatatype(Oid datatypeOid)` specifies a data type whose name and schema name should be included as auxiliary fields in the error report.
- `errdomainconstraint(Oid datatypeOid, const char *conname)` specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.
- `errcode_for_file_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved `errno` to determine which error code to generate. Usually this should be used in combination with `%m` in the primary error message text.
- `errcode_for_socket_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.
- `errhidestmt(bool hide_stmt)` can be called to specify suppression of the `STATEMENT:` portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.
- `errhidecontext(bool hide_ctx)` can be called to specify suppression of the `CONTEXT:` portion of a message in the postmaster log. This should only be used for verbose debugging messages where the repeated inclusion of context would bloat the log volume too much.

**Note**

At most one of the functions `errtable`, `errtablecol`, `errtableconstraint`, `errdatatype`, or `errdomainconstraint` should be used in an `ereport` call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it's likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

There is an older function `elog` that is still heavily used. An `elog` call:

```
elog(level, "format string", ...);
```

is exactly equivalent to:

```
ereport(level, (errmsg_internal("format string", ...)));
```

Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, `elog` should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through `ereport`. Nonetheless, there are enough internal “cannot happen” error checks in the system that `elog` is still widely used; it is preferred for those messages for its notational simplicity.

Advice about writing good error messages can be found in Section 54.3.

## 54.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by .

### What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail message if needed to keep the primary message short, or if you feel a need to mention implementation details such as the particular system call that failed. Both primary and detail messages should be factual. Use a hint message for suggestions about what to do to fix the problem, especially if the suggestion might not always be applicable.

For example, instead of:

```
IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m  
(plus a long addendum that is basically a hint)
```

write:

```
Primary:    could not create shared memory segment: %m  
Detail:    Failed syscall was shmget(key=%d, size=%u, 0%o).  
Hint:      the addendum
```

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen space on the assumption that one line is enough for error messages. Detail and hint messages can be relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would normally be suppressed from the server log to save space. Reference to implementation details is best avoided since users aren't expected to know the details.

### Formatting

Don't put any specific assumptions about formatting into the message texts. Expect clients and the server log to wrap lines to fit their own needs. In long messages, newline characters (`\n`) can be used to indicate suggested paragraph breaks. Don't end a message with a newline. Don't use tabs or other formatting

characters. (In error context displays, newlines are automatically added to separate levels of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or browsers these formatting instructions are at best ignored.

## Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should consistently use one kind of quotes that is consistent with publishing customs and computer output of other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the preferred use. Some have suggested choosing the kind of quotes depending on the type of object according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is a language-internal technical issue that many users aren't even familiar with, it won't scale to other kinds of quoted terms, it doesn't translate to other languages, and it's pretty pointless, too.

## Use of Quotes

Use quotes always to delimit file names, user-supplied identifiers, and other variables that might contain words. Do not use them to mark up variables that will not contain words (for example, operator names).

There are functions in the backend that will double-quote their own output at need (for example, `format_type_be()`). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don't clutter messages with unnecessary or duplicate quote marks.

## Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

Error context strings: Do not capitalize the first letter and do not end the string with a period. Context strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they're long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there's only one sentence.

## Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.

Rationale: It's easier to make everything look more consistent this way, since some messages are complete sentences and some not.

## Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject ("A could not do B"). Use telegram style without subject if the subject would be the program itself; do not use "I" for the program.

Rationale: The program is not human. Don't pretend otherwise.

## Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

```
could not open file "%s": %m
```

and:

```
cannot open file "%s"
```

The first one means that the attempt to open the file failed. The message should give a reason, such as "disk full" or "file doesn't exist". The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it's conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

## Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what "foo.bar.baz" refers to.

## Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.

## Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:

```
could not open file %s: %m
```

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it's unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

## Reasons for Errors

Messages should always state the reason why an error occurred. For example:

```
BAD:    could not open file %s  
BETTER: could not open file %s (I/O failure)
```

If no reason is known you better fix the code.

## Function Names

Don't include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it's not helpful information. If the error text doesn't make as much sense without the function name, reword it.

```
BAD:    pg_atoi: error in "z": cannot parse "z"  
BETTER: invalid input syntax for integer: "z"
```

Avoid mentioning called function names, either; instead say what the code was trying to do:

```
BAD:      open() failed: %m
BETTER:  could not open file %s: %m
```

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don't know what all those functions do.

## Tricky Words to Avoid

**Unable.** “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

**Bad.** Error messages like “bad result” are really hard to interpret intelligently. It's better to write why the result is “bad”, e.g., “invalid format”.

**Illegal.** “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it's invalid.

**Unknown.** Try to avoid “unknown”. Consider “error: unknown response”. If you don't know what the response is, how do you know it's erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

```
BAD:      unknown node type
BETTER:  unrecognized node type: 42
```

**Find vs. Exists.** If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn't “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn't “exist”. Using “find” in this case sounds weak and confuses the issue.

**May vs. Can vs. Might.** “May” suggests permission (e.g., “You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g., “I can lift that log.”), and “might” suggests possibility (e.g., “It might rain today.”). Using the proper word clarifies meaning and assists translation.

**Contractions.** Avoid contractions, like “can't”; use “cannot” instead.

## Proper Spelling

Spell out words in full. For instance, avoid:

- spec
- stats
- parens
- auth
- xact

Rationale: This will improve consistency.

## Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 55.2.2 to avoid making life difficult for translators.

## 54.4. Miscellaneous Coding Conventions

### C Standard

Code in should only rely on language features available in the C89 standard. That means a conforming C89 compiler has to be able to compile postgres, at least aside from a few platform dependent pieces.

Features from later revision of the C standard or compiler specific features can be used, if a fallback is provided.

For example `static inline` and `_StaticAssert()` are currently used, even though they are from newer revisions of the C standard. If not available we respectively fall back to defining the functions without `inline`, and to using a C89 compatible replacement that performs the same checks, but emits rather cryptic messages.

## Function-Like Macros and Inline Functions

Both, macros with arguments and `static inline` functions, may be used. The latter are preferable if there are multiple-evaluation hazards when written as a macro, as e.g. the case with

```
#define Max(x, y) ((x) > (y) ? (x) : (y))
```

or when the macro would be very long. In other cases it's only possible to use macros, or at least easier. For example because expressions of various types need to be passed to the macro.

When the definition of an inline function references symbols (i.e. variables, functions) that are only available as part of the backend, the function may not be visible when included from frontend code.

```
#ifndef FRONTEND
static inline MemoryContext
MemoryContextSwitchTo(MemoryContext context)
{
    MemoryContext old = CurrentMemoryContext;

    CurrentMemoryContext = context;
    return old;
}
#endif /* FRONTEND */
```

In this example `CurrentMemoryContext`, which is only available in the backend, is referenced and the function thus hidden with a `#ifndef FRONTEND`. This rule exists because some compilers emit references to symbols contained in inline functions even if the function is not used.

## Writing Signal Handlers

To be suitable to run inside a signal handler code has to be written very carefully. The fundamental problem is that, unless blocked, a signal handler can interrupt code at any time. If code inside the signal handler uses the same state as code outside chaos may ensue. As an example consider what happens if a signal handler tries to acquire a lock that's already held in the interrupted code.

Barring special arrangements code in signal handlers may only call `async-signal safe` functions (as defined in POSIX) and access variables of type `volatile sig_atomic_t`. A few functions in `postgres` are also deemed signal safe, importantly `SetLatch()`.

In most cases signal handlers should do nothing more than note that a signal has arrived, and wake up code running outside of the handler using a latch. An example of such a handler is the following:

```
static void
handle_sighup(SIGNAL_ARGS)
{
    int          save_errno = errno;

    got_SIGHUP = true;
    SetLatch(MyLatch);

    errno = save_errno;
}
```

`errno` is saved and restored because `SetLatch()` might change it. If that were not done interrupted code that's currently inspecting `errno` might see the wrong value.

---

# Chapter 55. Native Language Support

## 55.1. For the Translator

programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the effort. You do not have to be a programmer at all to do this. This section explains how to help.

### 55.1.1. Requirements

We won't judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the `--enable-nls` option. This will also check for the `libintl` library and the `msgfmt` program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs `xgettext` and `msgmerge`, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won't need `xgettext`. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local `gettext` implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

### 55.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in *message catalogs*, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is to no surprise either `.po` or `.mo`. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are `psql.po` (PO file for `psql`) or `fr.mo` (MO file in French).

The file format of the PO files is illustrated here:

```
# comment

msgid "original string"
msgstr "translated string"

msgid "more original"
msgstr "another translated"
"string can be broken up like this"

...
```

The `msgid`'s are extracted from the program source. (They need not be, but this is the most common way.) The `msgstr` lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The `#` character introduces a comment. If whitespace immediately follows the `#` character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-

whitespace character immediately following the `#`. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

```
#. automatic comment
#: filename.c:1023
#, flags, flags
```

The `#.` style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The `#:.` comment indicates the exact location(s) where the message is used in the source. The translator need not look at the program source, but can if there is doubt about the correct translation. The `#,` comments contain flags that describe the message in some way. There are currently two flags: `fuzzy` is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is `c-format`, which indicates that the message is a `printf`-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the `c-format` flag.

### 55.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file `nls.mk`, then this program has been prepared for translation.

If there are already some `.po` files, then someone has already done some translation work. The files are named `language.po`, where `language` is the *ISO 639-1 two-letter language code (in lower case)*, e.g., `fr.po` for French. If there is really a need for more than one translation effort per language then the files can also be named `language_region.po` where `region` is the *ISO 3166-1 two-letter country code (in upper case)*, e.g., `pt_BR.po` for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

```
make init-po
```

This will create a file `progname.pot`. (`.pot` to distinguish it from PO files that are “in production”. The `T` stands for “template”.) Copy this file to `language.po` and edit it. To make it known that the new language is available, also edit the file `nls.mk` and add the language (or language and country) code to the line that looks like:

```
AVAIL_LANGUAGES := de fr
```

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

```
make update-po
```

which will create a new blank message catalog file (the `pot` file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a `.po.new` extension.

### 55.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the `msgstr` directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a `printf` format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

```
msgstr "Die Datei %2$s hat %1$u Zeichen."
```

Then the first placeholder will actually use the second argument from the list. The `digits$` needs to follow the `%` immediately, before any other format manipulators. (This feature really exists in the `printf` family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.
- Maintain the style and tone of the original string. Specifically, messages that are not sentences (cannot open file %s) should probably not start with a capital letter (if your language distinguishes letter case) or end with a period (if your language uses punctuation marks). It might help to read Section 54.3.
- If you don't know what a message means, or if it is ambiguous, ask on the developers' mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it's best to improve the message.

## 55.2. For the Programmer

### 55.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the distribution. Currently, it only applies to C programs.

#### Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

```
#ifdef ENABLE_NLS
#include <locale.h>
#endif

...

#ifdef ENABLE_NLS
setlocale(LC_ALL, "");
bindtextdomain("progrname", LOCALEDIR);
textdomain("progrname");
#endif
```

(The `progrname` can actually be chosen freely.)

2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

```
fprintf(stderr, "panic level %d\n", lvl);
```

would be changed to:

```
fprintf(stderr, gettext("panic level %d\n"), lvl);
```

(`gettext` is defined as a no-op if NLS support is not configured.)

This tends to add a lot of clutter. One common shortcut is to use:

```
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:

```
CATALOG_NAME
```

The program name, as provided in the `textdomain()` call.

```
AVAIL_LANGUAGES
```

List of provided translations — initially empty.

```
GETTEXT_FILES
```

List of files that contain translatable strings, i.e., those marked with `gettext` or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a `+` and the second word be a file that contains one file name per line.

```
GETTEXT_TRIGGERS
```

The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only `gettext()` calls are known. If you used `_` or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form `func:2` (for the second argument). If you have a function that supports pluralized messages, the item should look like `func:1,2` (identifying the singular and plural message arguments).

The build system will automatically take care of building and installing the message catalogs.

## 55.2.2. Message-writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

- Do not construct sentences at run-time, like:

```
printf("Files were %s.\n", flag ? "copied" : "removed");
```

The word order within the sentence might be different in other languages. Also, even if you remember to call `gettext()` on each fragment, the fragments might not translate well separately. It's better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

- For similar reasons, this won't work:

```
printf("copied %d file%s", n, n!=1 ? "s" : "");
```

because it assumes how the plural is formed. If you figured you could solve it like this:

```
if (n==1)
    printf("copied 1 file");
else
    printf("copied %d files", n);
```

then be disappointed. Some languages have more than two forms, with some peculiar rules. It's often best to design the message to avoid the issue altogether, for instance like this:

```
printf("number of copied files: %d", n);
```

If you really want to construct a properly pluralized message, there is support for this, but it's a bit awkward. When generating a primary or detail error message in `ereport()`, you can write something like this:

```
errmsg_plural("copied %d file",
             "copied %d files",
             n,
             n)
```

The first argument is the format string appropriate for English singular form, the second is the format string appropriate for English plural form, and the third is the integer control value that determines which plural form to use. Subsequent arguments are formatted per the format string as usual. (Normally, the pluralization control value will also be one of the values to be formatted, so it has to be written twice.) In English it only matters whether  $n$  is 1 or not 1, but in other languages there can be many different plural forms. The translator sees the two English forms as a group and has the opportunity to supply multiple substitute strings, with the appropriate one being selected based on the run-time value of  $n$ .

If you need to pluralize a message that isn't going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the `gettext` documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

```
/* translator: This message is not what it seems to be. */
```

These comments are copied to the message catalog files so that the translators can see them.

---

# Chapter 56. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface) go through a *call handler* function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language's call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with as taking no arguments and returning the type `language_handler`. This special pseudo-type identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 38.9.

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoData` struct containing argument values and information about the called function, and it is expected to return a `Datum` result (and possibly set the `isnull` field of the `FunctionCallInfoData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It's up to the call handler to fetch the entry of the function from the `pg_proc` system catalog and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-`NULL` then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoData`'s `context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```
#include "postgres.h"
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"

#ifdef PG_MODULE_MAGIC
```

```
PG_MODULE_MAGIC;
#endif

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum
plsample_call_handler(PG_FUNCTION_ARGS)
{
    Datum          retval;

    if (CALLED_AS_TRIGGER(fcinfo))
    {
        /*
         * Called as a trigger procedure
         */
        TriggerData *trigdata = (TriggerData *) fcinfo->context;

        retval = ...
    }
    else
    {
        /*
         * Called as a function
         */

        retval = ...
    }

    return retval;
}
```

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see Section 38.9.5), the following commands then register the sample procedural language:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
AS 'filename'
LANGUAGE C;
CREATE LANGUAGE plsample
HANDLER plsample_call_handler;
```

Although providing a call handler is sufficient to create a minimal procedural language, there are two other functions that can optionally be provided to make the language more convenient to use. These are a *validator* and an *inline handler*. A validator can be provided to allow language-specific checking to be done during CREATE FUNCTION. An inline handler can be provided to allow the language to support anonymous code blocks executed via the DO command.

If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type `oid`. The validator's result is ignored, so it is customarily declared to return `void`. The validator will be called at the end of a CREATE FUNCTION command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function's `pg_proc` row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call `CheckFunctionValidatorAccess()` to diagnose explicit calls to the validator that the user could not achieve through CREATE FUNCTION. Typical checks then include verifying that the function's argument and result types are supported by the language, and that the function's body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal `ereport()` error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the `check_function_bodies` parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by `pg_dump` so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a `CREATE FUNCTION` command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core `CREATE FUNCTION` code only executes `SET` clauses attached to a function when `check_function_bodies` is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when `check_function_bodies` is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type `internal`. The inline handler's result is ignored, so it is customarily declared to return `void`. The inline handler will be called when a `DO` statement is executed specifying the procedural language. The parameter actually passed is a pointer to an `InlineCodeBlock` struct, which contains information about the `DO` statement's parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It's recommended that you wrap all these function declarations, as well as the `CREATE LANGUAGE` command itself, into an *extension* so that a simple `CREATE EXTENSION` command is sufficient to install the language. See Section 38.15 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the `src/pl` subdirectory of the source tree. The `CREATE LANGUAGE` reference page also has some useful details.

---

# Chapter 57. Writing A Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the `contrib` subdirectory of the source tree. The `CREATE FOREIGN DATA WRAPPER` reference page also has some useful details.

## Note

The SQL standard specifies an interface for writing foreign data wrappers. However, does not implement that API, because the effort to accommodate it into would be large, and the standard API hasn't gained wide adoption anyway.

## 57.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 38.9.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with as taking no arguments and returning the special pseudo-type `fdw_handler`. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 57.2.

The validator function is responsible for validating options given in `CREATE` and `ALTER` commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either `ForeignDataWrapperRelationId`, `ForeignServerRelationId`, `UserMappingRelationId`, or `ForeignTableRelationId`). If no validator function is supplied, options are not checked at object creation time or object alteration time.

## 57.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc'd `FdwRoutine` struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The `FdwRoutine` struct type is declared in `src/include/foreign/fdwapi.h`, which see for additional details.

### 57.2.1. FDW Routines For Scanning Foreign Tables

```
void
GetForeignRelSize (PlannerInfo *root,
                  RelOptInfo *baserel,
                  Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner's global information about the query; `baserel` is the planner's information about this table; and `foreigntableid` is the `pg_class` OID of the foreign table. (`foreigntableid` could be obtained from the planner data structures, but it's passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width.

See Section 57.4 for additional information.

```
void
GetForeignPaths (PlannerInfo *root,
                RelOptInfo *baserel,
                Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It's recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See Section 57.4 for additional information.

```
ForeignScan *
GetForeignPlan (PlannerInfo *root,
               RelOptInfo *baserel,
               Oid foreigntableid,
               ForeignPath *best_path,
               List *tlist,
               List *scan_clauses,
               Plan *outer_plan);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously produced by `GetForeignPaths`, `GetForeignJoinPaths`, or `GetForeignUpperPaths`), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreigntableid` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it's recommended to use `make_foreignscan` to build the `ForeignScan` node.

See Section 57.4 for additional information.

```
void
BeginForeignScan (ForeignScanState *node,
                 int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```

TupleTableSlot *
IterateForeignScan (ForeignScanState *node);

```

Fetch one row from the foreign source, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). Return NULL if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that 's executor doesn't care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```

void
ReScanForeignScan (ForeignScanState *node);

```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```

void
EndForeignScan (ForeignScanState *node);

```

End the scan and release resources. It is normally not important to release `palloc'd` memory, but for example open files and connections to remote servers should be cleaned up.

## 57.2.2. FDW Routines For Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables' data and doing the join locally), it should provide this callback function:

```

void
GetForeignJoinPaths (PlannerInfo *root,
                    RelOptInfo *joinrel,
                    RelOptInfo *outerrel,
                    RelOptInfo *innerrel,
                    JoinType jointype,
                    JoinPathExtraData *extra);

```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with `GetForeignPaths`, this function should generate `ForeignPath` path(s) for the supplied `joinrel`, and call `add_path` to add these paths to the set of paths considered for the join. But unlike `GetForeignPaths`, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

If a `ForeignPath` path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the `scanrelid` of the resulting `ForeignScan` plan node should be set to zero, since there is no single relation that it represents; instead, the `fs_relids` field of the `ForeignScan` node represents the set of relations that were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from

the system catalogs, the FDW must fill `fdw_scan_tlist` with an appropriate list of `TargetEntry` nodes, representing the set of columns it will supply at run time in the tuples it returns.

See Section 57.4 for additional information.

### 57.2.3. FDW Routines For Planning Post-Scan/Join Processing

If an FDW supports performing remote post-scan/join processing, such as remote aggregation, it should provide this callback function:

```
void
GetForeignUpperPaths (PlannerInfo *root,
                     UpperRelationKind stage,
                     RelOptInfo *input_rel,
                     RelOptInfo *output_rel);
```

Create possible access paths for *upper relation* processing, which is the planner's term for all post-scan/join query processing, such as aggregation, window functions, sorting, and table updates. This optional function is called during query planning. Currently, it is called only if all base relation(s) involved in the query belong to the same FDW. This function should generate `ForeignPath` path(s) for any post-scan/join processing that the FDW knows how to perform remotely, and call `add_path` to add these paths to the indicated upper relation. As with `GetForeignJoinPaths`, it is not necessary that this function succeed in creating any paths, since paths involving local processing are always possible.

The `stage` parameter identifies which post-scan/join step is currently being considered. `output_rel` is the upper relation that should receive paths representing computation of this step, and `input_rel` is the relation representing the input to this step. (Note that `ForeignPath` paths added to `output_rel` would typically not have any direct dependency on paths of the `input_rel`, since their processing is expected to be done externally. However, examining paths previously generated for the previous processing step can be useful to avoid redundant planning work.)

See Section 57.4 for additional information.

### 57.2.4. FDW Routines For Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```
void
AddForeignUpdateTargets (Query *parsetree,
                       RangeTblEntry *target_rte,
                       Relation target_relation);
```

`UPDATE` and `DELETE` operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an `UPDATE` or `DELETE`.

To do that, add `TargetEntry` items to `parsetree->targetList`, containing expressions for the extra values to be fetched. Each such entry must be marked `resjunk = true`, and must have a distinct `resname` that will identify it at execution time. Avoid using names matching `ctidN`, `wholerow`, or `wholerowN`, as the core system can generate junk columns of these names.

This function is called in the rewriter, not the planner, so the information available is a bit different from that available to the planning routines. `parsetree` is the parse tree for the `UPDATE` or `DELETE` command, while `target_rte` and `target_relation` describe the target foreign table.

If the `AddForeignUpdateTargets` pointer is set to `NULL`, no extra target expressions are added. (This will make it impossible to implement `DELETE` operations, though `UPDATE` may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```
List *
PlanForeignModify (PlannerInfo *root,
                  ModifyTable *plan,
                  Index resultRelation,
                  int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the `ModifyTable` plan node that performs the update action. This private information must have the form of a `List`, and will be delivered to `BeginForeignModify` during the execution stage.

`root` is the planner's global information about the query. `plan` is the `ModifyTable` plan node, which is complete except for the `fdwPrivLists` field. `resultRelation` identifies the target foreign table by its range table index. `subplan_index` identifies which target of the `ModifyTable` plan node this is, counting from zero; use this if you want to index into `plan->plans` or other substructure of the plan node.

See Section 57.4 for additional information.

If the `PlanForeignModify` pointer is set to `NULL`, no additional plan-time actions are taken, and the `fdw_private` list delivered to `BeginForeignModify` will be `NIL`.

```
void
BeginForeignModify (ModifyTableState *mtstate,
                  ResultRelInfo *rinfo,
                  List *fdw_private,
                  int subplan_index,
                  int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, `ExecForeignInsert`, `ExecForeignUpdate` or `ExecForeignDelete` will be called for each tuple to be inserted, updated, or deleted.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.) `fdw_private` contains the private data generated by `PlanForeignModify`, if any. `subplan_index` identifies which target of the `ModifyTable` plan node this is. `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignModify` and `EndForeignModify`.

If the `BeginForeignModify` pointer is set to `NULL`, no action is taken during executor startup.

```
TupleTableSlot *
ExecForeignInsert (EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Insert one tuple into the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the tuple to be inserted; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional "junk" columns. (The `planSlot` is typically of little interest for `INSERT` cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually inserted (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `INSERT` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignInsert` pointer is set to `NULL`, attempts to insert into the foreign table will fail with an error message.

```
TupleTableSlot *
ExecForeignUpdate (EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Update one tuple in the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the new data for the tuple; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional "junk" columns. In particular, any junk columns that were requested by `AddForeignUpdateTargets` will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually updated (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `UPDATE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignUpdate` pointer is set to `NULL`, attempts to update the foreign table will fail with an error message.

```
TupleTableSlot *
ExecForeignDelete (EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Delete one tuple from the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; in particular, it will carry any junk columns that were requested by `AddForeignUpdateTargets`. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or `NULL` if no row was deleted (typically as a result of triggers). The passed-in `slot` can be used to hold the tuple to be returned.

The data in the returned slot is used only if the `DELETE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignDelete` pointer is set to `NULL`, attempts to delete from the foreign table will fail with an error message.

```
void
EndForeignModify (EState *estate,
                 ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignModify` pointer is set to `NULL`, no action is taken during executor shutdown.

```
int
IsForeignRelUpdatable (Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the `CmdType` enumeration; that is,  $(1 \ll \text{CMD\_UPDATE}) = 4$  for UPDATE,  $(1 \ll \text{CMD\_INSERT}) = 8$  for INSERT, and  $(1 \ll \text{CMD\_DELETE}) = 16$  for DELETE.

If the `IsForeignRelUpdatable` pointer is set to `NULL`, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides `ExecForeignInsert`, `ExecForeignUpdate`, or `ExecForeignDelete` respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it's permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the `information_schema` views.)

Some inserts, updates, and deletes to foreign tables can be optimized by implementing an alternative set of interfaces. The ordinary interfaces for inserts, updates, and deletes fetch rows from the remote server and then modify those rows one at a time. In some cases, this row-by-row approach is necessary, but it can be inefficient. If it is possible for the foreign server to determine which rows should be modified without actually retrieving them, and if there are no local triggers which would affect the operation, then it is possible to arrange things so that the entire operation is performed on the remote server. The interfaces described below make this possible.

```
bool
PlanDirectModify (PlannerInfo *root,
                 ModifyTable *plan,
                 Index resultRelation,
                 int subplan_index);
```

Decide whether it is safe to execute a direct modification on the remote server. If so, return `true` after performing planning actions needed for that. Otherwise, return `false`. This optional function is called during query planning. If this function succeeds, `BeginDirectModify`, `IterateDirectModify` and `EndDirectModify` will be called at the execution stage, instead. Otherwise, the table modification will be executed using the table-updating functions described above. The parameters are the same as for `PlanForeignModify`.

To execute the direct modification on the remote server, this function must rewrite the target subplan with a `ForeignScan` plan node that executes the direct modification on the remote server. The `operation` field of the `ForeignScan` must be set to the `CmdType` enumeration appropriately; that is, `CMD_UPDATE` for UPDATE, `CMD_INSERT` for INSERT, and `CMD_DELETE` for DELETE.

See Section 57.4 for additional information.

If the `PlanDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
BeginDirectModify (ForeignScanState *node,
                 int eflags);
```

Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to `IterateDirectModify`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to modify is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-

private information provided by `PlanDirectModify`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when (`eflags & EXEC_FLAG_EXPLAIN_ONLY`) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainDirectModify` and `EndDirectModify`.

If the `BeginDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
TupleTableSlot *
IterateDirectModify (ForeignScanState *node);
```

When the `INSERT`, `UPDATE` or `DELETE` query doesn't have a `RETURNING` clause, just return `NULL` after a direct modification on the remote server. When the query has the clause, fetch one result containing the data needed for the `RETURNING` calculation, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). The data that was actually inserted, updated or deleted must be stored in the `es_result_relation_info->ri_projectReturning->pi_exprContext->ecxt_scantuple` of the node's `EState`. Return `NULL` if no more rows are available. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginDirectModify` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being updated. If you choose to optimize away fetching columns that are not needed for the `RETURNING` calculation, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Whether the query has the clause or not, the query's reported row count must be incremented by the FDW itself. When the query doesn't have the clause, the FDW must also increment the row count for the `ForeignScanState` node in the `EXPLAIN ANALYZE` case.

If the `IterateDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
EndDirectModify (ForeignScanState *node);
```

Clean up following a direct modification on the remote server. It is normally not important to release `palloc`'d memory, but for example open files and connections to the remote server should be cleaned up.

If the `EndDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

## 57.2.5. FDW Routines For Row Locking

If an FDW wishes to support *late row locking* (as described in Section 57.5), it must provide the following callback functions:

```
RowMarkType
GetForeignRowMarkType (RangeTblEntry *rte,
                      LockClauseStrength strength);
```

Report which row-marking option to use for a foreign table. `rte` is the `RangeTblEntry` node for the table and `strength` describes the lock strength requested by the relevant `FOR UPDATE/SHARE` clause, if any. The result must be a member of the `RowMarkType` enum type.

This function is called during query planning for each foreign table that appears in an `UPDATE`, `DELETE`, or `SELECT FOR UPDATE/SHARE` query and is not the target of `UPDATE` or `DELETE`.

If the `GetForeignRowMarkType` pointer is set to `NULL`, the `ROW_MARK_COPY` option is always used. (This implies that `RefetchForeignRow` will never be called, so it need not be provided either.)

See Section 57.5 for more information.

```
HeapTuple
RefetchForeignRow (EState *estate,
                  ExecRowMark *erm,
                  Datum rowid,
                  bool *updated);
```

Re-fetch one tuple from the foreign table, after locking it if required. `estate` is global execution state for the query. `erm` is the `ExecRowMark` struct describing the target foreign table and the row lock type (if any) to acquire. `rowid` identifies the tuple to be fetched. `updated` is an output parameter.

This function should return a `palloc`'ed copy of the fetched tuple, or `NULL` if the row lock couldn't be obtained. The row lock type to acquire is defined by `erm->markType`, which is the value previously returned by `GetForeignRowMarkType`. (`ROW_MARK_REFERENCE` means to just re-fetch the tuple without acquiring any lock, and `ROW_MARK_COPY` will never be seen by this routine.)

In addition, `*updated` should be set to `true` if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning `true` is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; a `NULL` return is only appropriate if the `SKIP LOCKED` option is specified by `erm->waitPolicy`.

The `rowid` is the `ctid` value previously read for the row to be re-fetched. Although the `rowid` value is passed as a `Datum`, it can currently only be a `tid`. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the `RefetchForeignRow` pointer is set to `NULL`, attempts to re-fetch rows will fail with an error message.

See Section 57.5 for more information.

```
bool
RecheckForeignScan (ForeignScanState *node, TupleTableSlot *slot);
```

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to `NULL` and instead set `fdw_recheck_qual` appropriately. When outer joins are pushed down, however, it isn't sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to `NULL`, rather than in no tuple being returned. `RecheckForeignScan` can recheck qualifiers and return `true` if they are still satisfied and `false` otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the `ForeignScan`. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops. The function `GetExistingLocalJoinPath` may be used to search existing paths for a suitable local join path, which can be used as the alternative local join plan. `GetExistingLocalJoinPath` searches for an unparameterized path in the path list of the specified join relation. (If it does not find such a path, it returns `NULL`, in which case a foreign data wrapper may build the local path by itself or may choose not to create access paths for that join.)

## 57.2.6. FDW Routines for EXPLAIN

```
void
ExplainForeignScan (ForeignScanState *node,
                  ExplainState *es);
```

Print additional `EXPLAIN` output for a foreign table scan. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine

what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case.

If the `ExplainForeignScan` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

```
void
ExplainForeignModify (ModifyTableState *mtstate,
                     ResultRelInfo *rinfo,
                     List *fdw_private,
                     int subplan_index,
                     struct ExplainState *es);
```

Print additional `EXPLAIN` output for a foreign table update. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ModifyTableState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case. The first four arguments are the same as for `BeginForeignModify`.

If the `ExplainForeignModify` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

```
void
ExplainDirectModify (ForeignScanState *node,
                    ExplainState *es);
```

Print additional `EXPLAIN` output for a direct modification on the remote server. This function can call `ExplainPropertyText` and related functions to add fields to the `EXPLAIN` output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the `EXPLAIN ANALYZE` case.

If the `ExplainDirectModify` pointer is set to `NULL`, no additional information is printed during `EXPLAIN`.

### 57.2.7. FDW Routines for ANALYZE

```
bool
AnalyzeForeignTable (Relation relation,
                    AcquireSampleRowsFunc *func,
                    BlockNumber *totalpages);
```

This function is called when `ANALYZE` is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return `true`, and provide a pointer to a function that will collect sample rows from the table in `func`, plus the estimated size of the table in pages in `totalpages`. Otherwise, return `false`.

If the FDW does not support collecting statistics for any tables, the `AnalyzeForeignTable` pointer can be set to `NULL`.

If provided, the sample collection function must have the signature

```
int
AcquireSampleRowsFunc (Relation relation, int elevel,
                      HeapTuple *rows, int targrows,
                      double *totalrows,
                      double *totaldeadrows);
```

A random sample of up to `targrows` rows should be collected from the table and stored into the caller-provided `rows` array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters `totalrows` and `totaldeadrows`. (Set `totaldeadrows` to zero if the FDW does not have any concept of dead rows.)

### 57.2.8. FDW Routines For IMPORT FOREIGN SCHEMA

```
List *
```

```
ImportForeignSchema (ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing `IMPORT FOREIGN SCHEMA`, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a `CREATE FOREIGN TABLE` command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: `FDW_IMPORT_SCHEMA_ALL` means that all tables in the remote schema should be imported (in this case `table_list` is empty), `FDW_IMPORT_SCHEMA_LIMIT_TO` means to include only tables listed in `table_list`, and `FDW_IMPORT_SCHEMA_EXCEPT` means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the `NOT NULL` attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed `CREATE FOREIGN TABLE` commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it's often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to `NULL`.

## 57.2.9. FDW Routines for Parallel Execution

A `ForeignScan` node can, optionally, support parallel execution. A parallel `ForeignScan` will be executed in multiple processes and must return each row exactly once across all cooperating processes. To do this, processes can coordinate through fixed-size chunks of dynamic shared memory. This shared memory is not guaranteed to be mapped at the same address in every process, so it must not contain pointers. The following functions are all optional, but most are required if parallel execution is to be supported.

```
bool
IsForeignScanParallelSafe(PlannerInfo *root, RelOptInfo *rel,
                          RangeTblEntry *rte);
```

Test whether a scan can be performed within a parallel worker. This function will only be called when the planner believes that a parallel plan might be possible, and should return true if it is safe for that scan to run within a parallel worker. This will generally not be the case if the remote data source has transaction semantics, unless the worker's connection to the data can somehow be made to share the same transaction context as the leader.

If this function is not defined, it is assumed that the scan must take place within the parallel leader. Note that returning true does not mean that the scan itself can be done in parallel, only that the scan can be performed within a parallel worker. Therefore, it can be useful to define this method even when parallel execution is not supported.

```
Size
EstimateDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This function is optional, and can be omitted if not needed; but if it is omitted, the next three functions must be omitted as well, because no shared memory will be allocated for the FDW's use.

```
void
```

```
InitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt,
                        void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimateDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void
ReInitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt,
                          void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the foreign-scan plan node is about to be re-scanned. This function is optional, and can be omitted if not needed. Recommended practice is that this function reset only shared state, while the `ReScanForeignScan` function resets only local state. Currently, this function will be called before `ReScanForeignScan`, but it's best not to rely on that ordering.

```
void
InitializeWorkerForeignScan(ForeignScanState *node, shm_toc *toc,
                          void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializeDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void
ShutdownForeignScan(ForeignScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndForeignScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, foreign data wrappers that wish to take some action before the DSM segment goes away should implement this method.

## 57.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file `foreign/foreign.h` in your source file. That header also defines the struct types that are returned by these functions.

```
ForeignDataWrapper *
GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see `foreign/foreign.h` for details).

```
ForeignServer *
GetForeignServer(Oid serverid);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see `foreign/foreign.h` for details).

```
UserMapping *
GetUserMapping(Oid userid, Oid serverid);
```

This function returns a `UserMapping` object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for `PUBLIC`, or throw error if there is none.) A `UserMapping` object contains properties of the user mapping (see `foreign/foreign.h` for details).

```
ForeignTable *
GetForeignTable(Oid relid);
```

This function returns a `ForeignTable` object for the foreign table with the given OID. A `ForeignTable` object contains properties of the foreign table (see `foreign/foreign.h` for details).

```
List *
GetForeignColumnOptions(Oid relid, AttrNumber attnum);
```

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of `DefElem`. NIL is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

```
ForeignDataWrapper *
GetForeignDataWrapperByName(const char *name, bool missing_ok);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if `missing_ok` is true, otherwise raise an error.

```
ForeignServer *
GetForeignServerByName(const char *name, bool missing_ok);
```

This function returns a `ForeignServer` object for the foreign server with the given name. If the server is not found, return NULL if `missing_ok` is true, otherwise raise an error.

## 57.4. Foreign Data Wrapper Query Planning

The FDW callback functions `GetForeignRelSize`, `GetForeignPaths`, `GetForeignPlan`, `PlanForeignModify`, `GetForeignJoinPaths`, `GetForeignUpperPaths`, and `PlanDirectModify` must fit into the workings of the planner. Here are some notes about what they must do.

The information in `root` and `baserel` can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). `baserel->baserestrictinfo` is particularly interesting, as it contains restriction quals (`WHERE` clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) `baserel->reltarget->exprs` can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the `ForeignScan` plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be `palloc'd`, so that it will be reclaimed at the end of planning.

`baserel->fdw_private` is a void pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to NULL when the `RelOptInfo` node is created. It is useful for passing information forward from `GetForeignRelSize` to `GetForeignPaths` and/or `GetForeignPaths` to `GetForeignPlan`, thereby avoiding recalculation.

`GetForeignPaths` can identify the meaning of different access paths by storing private information in the `fdw_private` field of `ForeignPath` nodes. `fdw_private` is declared as a `List` pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that's dumpable by `nodeToString`, for use with debugging support available in the backend.

`GetForeignPlan` can examine the `fdw_private` field of the selected `ForeignPath` node, and can generate `fdw_exprs` and `fdw_private` lists to be placed in the `ForeignScan` plan node, where they will be available at execution time. Both of these lists must be represented in a form that `copyObject` knows how to copy. The `fdw_private` list has no other restrictions and is not interpreted by the core backend in any way. The `fdw_exprs` list, if not NIL, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In `GetForeignPlan`, generally the passed-in target list can be copied into the plan node as-is. The passed `scan_clauses` list contains the same clauses as `baserel->baserestrictinfo`, but may be re-ordered

for better execution efficiency. In simple cases the FDW can just strip `RestrictInfo` nodes from the `scan_clauses` list (using `extract_actual_clauses`) and put all the clauses into the plan node's qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node's qual list so that the executor doesn't waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form `foreign_variable = sub_expression`, which it determines can be executed on the remote server given the locally-evaluated value of the `sub_expression`. The actual identification of such a clause should happen during `GetForeignPaths`, since it would affect the cost estimate for the path. The path's `fdw_private` field would probably include a pointer to the identified clause's `RestrictInfo` node. Then `GetForeignPlan` would remove that clause from `scan_clauses`, but add the `sub_expression` to `fdw_exprs` to ensure that it gets massaged into executable form. It would probably also put control information into the plan node's `fdw_private` field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like `WHERE foreign_variable = $1`, with the parameter value obtained at run time from evaluation of the `fdw_exprs` expression tree.

Any clauses removed from the plan node's qual list must instead be added to `fdw_recheckquals` or rechecked by `RecheckForeignScan` in order to ensure correct behavior at the `READ COMMITTED` isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using `fdw_recheckquals` is typically easier than implementing checks inside `RecheckForeignScan`, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to `NULL` without rejecting the tuple entirely.

Another `ForeignScan` field that can be filled by FDWs is `fdw_scan_tlist`, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to `NIL`, implying that the returned tuples have the row type declared for the foreign table. A non-`NIL` value must be a target list (list of `TargetEntry`s) containing `Vars` and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won't be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to `fdw_scan_tlist`. Note that join plans (created from paths made by `GetForeignJoinPaths`) must always supply `fdw_scan_tlist` to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table's restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example `foreign_variable = local_variable`. Such clauses will not be found in `baserel->baserestrictinfo` but must be sought in the relation's join lists. A path using such a clause is called a "parameterized path". It must identify the other relations used in the selected join clause(s) with a suitable value of `param_info`; use `get_baserel_parampathinfo` to compute that value. In `GetForeignPlan`, the `local_variable` portion of the join clause would be added to `fdw_exprs`, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, `GetForeignJoinPaths` should produce `ForeignPaths` for potential remote joins in much the same way as `GetForeignPaths` works for base tables. Information about the intended join can be passed forward to `GetForeignPlan` in the same ways described above. However, `baserestrictinfo` is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to `GetForeignJoinPaths` as a separate parameter (`extra->restrictlist`).

An FDW might additionally support direct execution of some plan actions that are above the level of scans and joins, such as grouping or aggregation. To offer such options, the FDW should generate paths and insert them into the appropriate *upper relation*. For example, a path representing remote aggregation should be inserted into the `UPPERREL_GROUP_AGG` relation, using `add_path`. This path will be compared on a cost basis with local aggregation performed by reading a simple scan path for the foreign relation (note that such a path must also be supplied, else there will be an error at plan time). If the remote-aggregation path wins, which it usually would, it will be converted into a plan in the usual way, by calling `GetForeignPlan`. The recommended place to generate such paths is in the `GetForeignUpperPaths` call-

back function, which is called for each upper relation (i.e., each post-scan/join processing step), if all the base relations of the query come from the same FDW.

`PlanForeignModify` and the other callbacks described in Section 57.2.4 are designed around the assumption that the foreign relation will be scanned in the usual way and then individual row updates will be driven by a local `ModifyTable` plan node. This approach is necessary for the general case where an update requires reading local tables as well as foreign tables. However, if the operation could be executed entirely by the foreign server, the FDW could generate a path representing that and insert it into the `UPPERREL_FINAL` upper relation, where it would compete against the `ModifyTable` approach. This approach could also be used to implement remote `SELECT FOR UPDATE`, rather than using the row locking callbacks described in Section 57.2.5. Keep in mind that a path inserted into `UPPERREL_FINAL` is responsible for implementing *all* behavior of the query.

When planning an `UPDATE` or `DELETE`, `PlanForeignModify` and `PlanDirectModify` can look up the `RelOptInfo` struct for the foreign table and make use of the `baserel->fdw_private` data previously created by the scan-planning functions. However, in `INSERT` the target table is not scanned so there is no `RelOptInfo` for it. The `List` returned by `PlanForeignModify` has the same restrictions as the `fdw_private` list of a `ForeignScan` plan node, that is it must contain only structures that `copyObject` knows how to copy.

`INSERT` with an `ON CONFLICT` clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that `ON CONFLICT DO UPDATE` is not supported, since the specification is mandatory there.

## 57.5. Row Locking in Foreign Data Wrappers

If an FDW's underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform *early locking* or *late locking*. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as TIDs do.

By default, ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in Section 57.2.5, which were added in 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in `READ COMMITTED` isolation mode, may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an `UPDATE` or `DELETE` on a foreign table, it is recommended that the `ForeignScan` operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of `SELECT FOR UPDATE`. An FDW can detect whether a table is an `UPDATE/DELETE` target at plan time by comparing its `relid` to `root->parse->resultRelation`, or at execution time by using `ExecRelationIsTargetRelation()`. An

alternative possibility is to perform late locking within the `ExecForeignUpdate` or `ExecForeignDelete` callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a `SELECT FOR UPDATE/SHARE` command, the `ForeignScan` operation can again perform early locking by fetching tuples with the equivalent of `SELECT FOR UPDATE/SHARE`. To perform late locking instead, provide the callback functions defined in Section 57.2.5. In `GetForeignRowMarkType`, select rowmark option `ROW_MARK_EXCLUSIVE`, `ROW_MARK_NOKEYEXCLUSIVE`, `ROW_MARK_SHARE`, or `ROW_MARK_KEYSHARE` depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using `get_plan_rowmark` at plan time, or `ExecFindRowMark` at execution time; you must check not only whether a non-null rowmark struct is returned, but that its `strength` field is not `LCS_NONE`.

Lastly, for foreign tables that are used in an `UPDATE`, `DELETE` or `SELECT FOR UPDATE/SHARE` command but are not specified to be row-locked, you can override the default choice to copy entire rows by having `GetForeignRowMarkType` select option `ROW_MARK_REFERENCE` when it sees lock strength `LCS_NONE`. This will cause `RefetchForeignRow` to be called with that value for `markType`; it should then re-fetch the row without acquiring any new lock. (If you have a `GetForeignRowMarkType` function but don't wish to re-fetch unlocked rows, select option `ROW_MARK_COPY` for `LCS_NONE`.)

See `src/include/nodes/lockoptions.h`, the comments for `RowMarkType` and `PlanRowMark` in `src/include/nodes/plannodes.h`, and the comments for `ExecRowMark` in `src/include/nodes/execnodes.h` for additional information.

---

# Chapter 58. Writing A Table Sampling Method

's implementation of the `TABLESAMPLE` clause supports custom table sampling methods, in addition to the `BERNOULLI` and `SYSTEM` methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the `TABLESAMPLE` clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the `TABLESAMPLE` clause. The `internal` argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from a SQL command. The result of the function must be a palloc'd struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 58.1.

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

```
List *parameterTypes
```

This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the `TABLESAMPLE` clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

```
bool repeatable_across_queries
```

If `true`, the sampling method can deliver identical samples across successive queries, if the same parameters and `REPEATABLE` seed value are supplied each time and the table contents have not changed. When this is `false`, the `REPEATABLE` clause is not accepted for use with the sampling method.

```
bool repeatable_across_scans
```

If `true`, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is `false`, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The `TsmRoutine` struct type is declared in `src/include/access/tsmapi.h`, which see for additional details.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `src/backend/access/tablesample` subdirectory of the source tree for the built-in sampling methods, and into the `contrib` subdirectory for add-on methods.

## 58.1. Sampling Method Support Functions

The TSM handler function returns a palloc'd `TsmRoutine` struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those pointers can be `NULL`.

```
void
SampleScanGetSampleSize (PlannerInfo *root,
                        RelOptInfo *baserel,
                        List *paramexprs,
                        BlockNumber *pages,
```

```
double *tuples);
```

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these might be determined by estimating the sampling fraction, and then multiplying the `basere1->pages` and `basere1->tuples` numbers by that, being sure to round the results to integral values.) The `paramexprs` list holds the expression(s) that are parameters to the `TABLESAMPLE` clause. It is recommended to use `estimate_expression_value()` to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they're only estimates of what the run-time values will be). The `pages` and `tuples` parameters are outputs.

```
void
InitSampleScan (SampleScanState *node,
               int eflags);
```

Initialize for execution of a `SampleScan` plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The `SampleScanState` node has already been created, but its `tsm_state` field is `NULL`. The `InitSampleScan` function can `malloc` whatever internal state data is needed by the sampling method, and store a pointer to it in `node->tsm_state`. Information about the table to scan is accessible through other fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). `eflags` contains flag bits describing the executor's operating mode for this plan node.

When `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for `EXPLAIN` and `EndSampleScan`.

This function can be omitted (set the pointer to `NULL`), in which case `BeginSampleScan` must perform all initialization needed by the sampling method.

```
void
BeginSampleScan (SampleScanState *node,
                Datum *params,
                int nparams,
                uint32 seed);
```

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). The `params` array, of length `nparams`, contains the values of the parameters supplied in the `TABLESAMPLE` clause. These will have the number and types specified in the sampling method's `parameterTypes` list, and have been checked to not be null. `seed` contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the `REPEATABLE` value if one was given, or the result of `random()` if not.

This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to `false` if the scan will visit only a small fraction of the table's pages. If `node->use_pagemode` is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to `false` if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don't change).

```
BlockNumber
```

```
NextSampleBlock (SampleScanState *node);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to `NULL`), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```
OffsetNumber  
NextSampleTuple (SampleScanState *node,  
                BlockNumber blockno,  
                OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

### Note

`NextSampleTuple` is not explicitly told which of the offset numbers in the range `1 .. maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can examine `node->ss.ss_currentScanDesc->rs_vistuples[]` to identify which tuples are valid and visible. (This requires `node->use_pagemode` to be `true`.)

### Note

`NextSampleTuple` must *not* assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

```
void  
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release `palloc'd` memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to `NULL`) in the common case where no such resources exist.

---

# Chapter 59. Writing A Custom Scan Provider

supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a foreign data wrapper, which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

## 59.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated what it believes to be the complete and correct set of access paths for the relation.

```
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
                                           RelOptInfo *rel,
                                           Index rti,
                                           RangeTblEntry *rte);

extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```
typedef struct CustomPath
{
    Path      path;
    uint32    flags;
    List      *custom_paths;
    List      *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which should include `CUSTOMPATH_SUPPORT_BACKWARD_SCAN` if the custom path can support a backward scan and `CUSTOMPATH_SUPPORT_MARK_RESTORE` if it can support mark and restore. Both capabilities are optional. An optional `custom_paths` is a list of `Path` nodes used by this custom-path node; these will be transformed into `Plan` nodes by planner. `custom_private` can be used to store the custom path's private data. Private data should be stored in a form that can be handled by `nodeToString`, so that debugging routines that attempt to print the custom path will work as designed. `methods` must point to a (usually statically allocated) object implementing the required custom path methods, of which there is currently only one. The `LibraryName` and `SymbolName` fields must also be initialized so that the dynamic loader can resolve them to locate the method table.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create `CustomPath` path(s) for the join relation.

```
typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
                                             RelOptInfo *joinrel,
```

```

                                RelOptInfo *outerrel,
                                RelOptInfo *innerrel,
                                JoinType jointype,
                                JoinPathExtraData *extra);
extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;

```

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

### 59.1.1. Custom Scan Path Callbacks

```

Plan *(*PlanCustomPath) (PlannerInfo *root,
                        RelOptInfo *rel,
                        CustomPath *best_path,
                        List *tlist,
                        List *clauses,
                        List *custom_plans);

```

Convert a custom path to a finished plan. The return value will generally be a `CustomScan` object, which the callback must allocate and initialize. See Section 59.2 for more details.

## 59.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```

typedef struct CustomScan
{
    Scan        scan;
    uint32      flags;
    List        *custom_plans;
    List        *custom_exprs;
    List        *custom_private;
    List        *custom_scan_tlist;
    Bitmapset   *custom_relids;
    const CustomScanMethods *methods;
} CustomScan;

```

`scan` must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. `flags` is a bit mask with the same meaning as in `CustomPath`. `custom_plans` can be used to store child `Plan` nodes. `custom_exprs` should be used to store expression trees that will need to be fixed up by `setrefs.c` and `subselect.c`, while `custom_private` should be used to store other private data that is only used by the custom scan provider itself. `custom_scan_tlist` can be `NIL` when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation's row type. Otherwise it is a target list describing the actual scan tuples. `custom_scan_tlist` must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. `custom_relids` is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. `methods` must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a `CustomScan` scans a single relation, `scan.scanrelid` must be the range table index of the table to be scanned. When it replaces a join, `scan.scanrelid` should be zero.

Plan trees must be able to be duplicated using `copyObject`, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a `CustomScan` for the structure itself, as would be possible for a `CustomPath` or `CustomScanState`.

### 59.2.1. Custom Scan Plan Callbacks

```

Node *(*CreateCustomScanState) (CustomScan *cscan);

```

Allocate a `CustomScanState` for this `CustomScan`. The actual allocation will often be larger than required for an ordinary `CustomScanState`, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and methods set appropriately, but other fields should be left as zeroes at this stage; after `ExecInitCustomScan` performs basic initialization, the `BeginCustomScan` callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

## 59.3. Executing Custom Scans

When a `CustomScan` is executed, its execution state is represented by a `CustomScanState`, which is declared as follows:

```
typedef struct CustomScanState
{
    ScanState ss;
    uint32    flags;
    const CustomExecMethods *methods;
} CustomScanState;
```

`ss` is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, `ss.ss_currentRelation` is left `NULL`. `flags` is a bit mask with the same meaning as in `CustomPath` and `CustomScan`. `methods` must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a `CustomScanState`, which need not support `copyObject`, will actually be a larger structure embedding the above as its first member.

### 59.3.1. Custom Scan Execution Callbacks

```
void (*BeginCustomScan) (CustomScanState *node,
                        Estate *estate,
                        int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by `ExecInitCustomScan`, but any private fields should be initialized here.

```
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next tuple in the current scan direction, and then return the tuple slot. If not, `NULL` or an empty slot should be returned.

```
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

```
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
Size (*EstimateDSMCustomScan) (CustomScanState *node,
                              ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in

bytes. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*InitializeDSMCustomScan) (CustomScanState *node,
                                ParallelContext *pcxt,
                                void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimateDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ReInitializeDSMCustomScan) (CustomScanState *node,
                                   ParallelContext *pcxt,
                                   void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the custom-scan plan node is about to be re-scanned. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution. Recommended practice is that this callback reset only shared state, while the `ReScanCustomScan` callback resets only local state. Currently, this callback will be called before `ReScanCustomScan`, but it's best not to rely on that ordering.

```
void (*InitializeWorkerCustomScan) (CustomScanState *node,
                                    shm_toc *toc,
                                    void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializeDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ShutdownCustomScan) (CustomScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndCustomScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, custom scan providers that wish to take some action before the DSM segment goes away should implement this method.

```
void (*ExplainCustomScan) (CustomScanState *node,
                           List *ancestors,
                           ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.

---

# Chapter 60. Genetic Query Optimizer

## Author

Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

## 60.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in ) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in ) as access paths for relations.

The normal query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

## 60.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a *population of individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors.

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current `geqo_seed` parameter setting. As long as `geqo_seed` and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing `geqo_seed`.

### 60.3.2. Future Implementation Tasks for GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file `src/backend/optimizer/geqo/geqo_main.c`, routines `gimme_pool_size` and `gimme_number_generations`, we have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner's join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

## 60.4. Further Reading

The following resources contain additional information about genetic algorithms:

# Chapter 61. Index Access Method Interface Definition

This chapter defines the interface between the core system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 67.6, and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see Section 67.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

## 61.1. Basic API Structure for Indexes

Each index access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the access method. These entries can be created and deleted using the `CREATE ACCESS METHOD` and `DROP ACCESS METHOD` SQL commands.

An index access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `index_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a palloc'd struct of type `IndexAmRoutine`, which contains everything that the core code needs to know to make use of the index access method. The `IndexAmRoutine` struct, also called the access method's *API struct*, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicolumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 61.2.

The structure `IndexAmRoutine` is defined thus:

```
typedef struct IndexAmRoutine
{
    NodeTag      type;

    /*
     * Total number of strategies (operators) by which we can traverse/search
     * this AM. Zero if AM does not have a fixed set of strategy assignments.
     */
    uint16      amstrategies;
    /* total number of support functions that this AM uses */
    uint16      amsupport;
    /* does AM support ORDER BY indexed column's value? */
    bool        amcanorder;
    /* does AM support ORDER BY result of an operator on indexed column? */

```

## Index Access Method Interface Definition

---

```
bool        amcanorderbyop;
/* does AM support backward scanning? */
bool        amcanbackward;
/* does AM support UNIQUE indexes? */
bool        amcanunique;
/* does AM support multi-column indexes? */
bool        amcanmulticol;
/* does AM require scans to have a constraint on the first index column? */
bool        amoptionalkey;
/* does AM handle ScalarArrayOpExpr quals? */
bool        amsearcharray;
/* does AM handle IS NULL/IS NOT NULL quals? */
bool        amsearchnulls;
/* can index storage data type differ from column data type? */
bool        amstorage;
/* can an index of this type be clustered on? */
bool        amclusterable;
/* does AM handle predicate locks? */
bool        ampredlocks;
/* does AM support parallel scan? */
bool        amcanparallel;
/* type of data stored in index, or InvalidOid if variable */
Oid         amkeytype;
/* does AM support columns included with clause INCLUDE? */
bool        amcaninclude;

/* interface functions */
ambuild_function ambuild;
ambuildempty_function ambuildempty;
aminert_function aminert;
ambulkdelete_function ambulkdelete;
amvacuumcleanup_function amvacuumcleanup;
amcanreturn_function amcanreturn; /* can be NULL */
amcostestimate_function amcostestimate;
amoptions_function amoptions;
amproperty_function amproperty; /* can be NULL */
amvalidate_function amvalidate;
ambeginscan_function ambeginscan;
amrescan_function amrescan;
amgettuple_function amgettuple; /* can be NULL */
amgetbitmap_function amgetbitmap; /* can be NULL */
amendscan_function amendscan;
ammarkpos_function ammarkpos; /* can be NULL */
amrestrpos_function amrestrpos; /* can be NULL */

/* interface functions to support parallel index scans */
amestimateparallelscan_function amestimateparallelscan; /* can be NULL */
aminrtparallelscan_function aminrtparallelscan; /* can be NULL */
amparallelrescan_function amparallelrescan; /* can be NULL */
} IndexAmRoutine;
```

To be useful, an index access method must also have one or more *operator families* and *operator classes* defined in `pg_opfamily`, `pg_opclass`, `pg_amop`, and `pg_amproc`. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 38.14, which is prerequisite material for reading this chapter.

An individual index is defined by a `pg_class` entry that describes it as a physical relation, plus a `pg_index` entry that shows the logical content of the index — that is, the set of index columns it has and the

semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in `pg_index`. Both of these catalog entries can be accessed as part of the `Relation` data structure that is passed to all operations on the index.

Some of the flag fields of `IndexAmRoutine` have nonobvious implications. The requirements of `amcanunique` are discussed in Section 61.5. The `amcanmulticol` flag asserts that the access method supports multicolumn indexes, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns *must* support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. One reason that an index AM might set `amoptionalkey` false is if it doesn't index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns *must* support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set `amsearchnulls`, indicating that it supports `IS NULL` and `IS NOT NULL` clauses as search conditions.

## 61.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide in `IndexAmRoutine` are:

```
IndexBuildResult *
ambuild (Relation heapRelation,
         Relation indexRelation,
         IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `IndexBuildHeapScan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc'd struct containing statistics about the new index.

```
void
ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (`INIT_FORKNUM`) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```
bool
aminsert (Relation indexRelation,
          Datum *values,
          bool *isnull,
          ItemPointer heap_tid,
          Relation heapRelation,
          IndexUniqueCheck checkUnique,
          IndexInfo *indexInfo);
```

Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `amcanunique` flag is true) then `checkUnique` indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see Section 61.5 for details. Normally the access method only needs the `heapRelation` parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The function's Boolean result value is significant only when `checkUnique` is `UNIQUE_CHECK_PARTIAL`. In this case a TRUE result means the new entry is known unique, whereas FALSE means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant FALSE result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, `aminsert` should just return without doing anything.

If the index AM wishes to cache data across successive index insertions within a SQL statement, it can allocate space in `indexInfo->ii_Context` and store a pointer to the data in `indexInfo->ii_AmCache` (which will be NULL initially).

```
IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
              IndexBulkDeleteResult *stats,
              IndexBulkDeleteCallback callback,
              void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state)` returns `bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc'd struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is NULL for the first call within a `VACUUM` operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

```
IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
                 IndexBulkDeleteResult *stats);
```

Clean up after a `VACUUM` operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or NULL if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc'd struct. The statistics it contains will be used to update `pg_class`, and will be reported by `VACUUM` if `VERBOSE` is given. It is OK to return NULL if the index was not changed at all during the `VACUUM` operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, `amvacuumcleanup` will also be called at completion of an `ANALYZE` operation. In this case `stats` is always NULL and any return value will be ignored. This case can be distinguished by checking `info->analyze_only`. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```
bool
amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support *index-only scans* on the given column, by returning the indexed column values for an index entry in the form of an `IndexTuple`. The attribute number is 1-based, i.e. the

## Index Access Method Interface Definition

---

first column's attno is 1. Returns TRUE if supported, else FALSE. If the access method does not support index-only scans at all, the `amcanreturn` field in its `IndexAmRoutine` struct can be set to NULL.

```
void
amcostestimate (PlannerInfo *root,
                IndexPath *path,
                double loop_count,
                Cost *indexStartupCost,
                Cost *indexTotalCost,
                Selectivity *indexSelectivity,
                double *indexCorrelation);
```

Estimate the costs of an index scan. This function is described fully in Section 61.6, below.

```
bytea *
amoptions (ArrayType *reloptions,
           bool validate);
```

Parse and validate the `reloptions` array for an index. This is called only when a non-null `reloptions` array exists for the index. `reloptions` is a text array containing entries of the form `name=value`. The function should construct a `bytea` value, which will be copied into the `rd_options` field of the index's `relcache` entry. The data contents of the `bytea` value are open for the access method to define; most of the standard access methods use struct `StdRdOptions`. When `validate` is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when `validate` is false, invalid entries should be silently ignored. (`validate` is false when loading options already stored in `pg_catalog`; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

```
bool
amproperty (Oid index_oid, int attno,
            IndexAMProperty prop, const char *propname,
            bool *res, bool *isnull);
```

The `amproperty` method allows index access methods to override the default behavior of `pg_index_column_has_property` and related functions. If the access method does not have any special behavior for index property inquiries, the `amproperty` field in its `IndexAmRoutine` struct can be set to NULL. Otherwise, the `amproperty` method will be called with `index_oid` and `attno` both zero for `pg_indexam_has_property` calls, or with `index_oid` valid and `attno` zero for `pg_index_has_property` calls, or with `index_oid` valid and `attno` greater than zero for `pg_index_column_has_property` calls. `prop` is an enum value identifying the property being tested, while `propname` is the original property name string. If the core code does not recognize the property name then `prop` is `AMPROP_UNKNOWN`. Access methods can define custom property names by checking `propname` for a match (use `pg_strcasecmp` to match, for consistency with the core code); for names known to the core code, it's better to inspect `prop`. If the `amproperty` method returns `true` then it has determined the property test result: it must set `*res` to the boolean value to return, or set `*isnull` to `true` to return a NULL. (Both of the referenced variables are initialized to `false` before the call.) If the `amproperty` method returns `false` then the core code will proceed with its normal logic for determining the property test result.

Access methods that support ordering operators should implement `AMPROP_DISTANCE_ORDERABLE` property testing, as the core code does not know how to do that and will return NULL. It may also be advantageous to implement `AMPROP_RETURNABLE` testing, if that can be done more cheaply than by opening the index and calling `amcanreturn`, which is the core code's default behavior. The default behavior should be satisfactory for all other standard properties.

```
bool
amvalidate (Oid opclassoid);
```

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do that. For example, this might include testing that all required support functions are provided. The

## Index Access Method Interface Definition

---

`amvalidate` function must return false if the opclass is invalid. Problems should be reported with `ereport` messages.

The purpose of an index, of course, is to support scans for tuples matching an indexable `WHERE` condition, often called a *qualifier* or *scan key*. The semantics of index scanning are described more fully in Section 61.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```
IndexScanDesc
ambeginscan (Relation indexRelation,
            int nkeys,
            int norderbys);
```

Prepare for an index scan. The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren't provided yet. The result must be a palloc'd struct. For implementation reasons the index access method *must* create this struct by calling `RelationGetIndexScan()`. In most cases `ambeginscan` does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

```
void
amrescan (IndexScanDesc scan,
         ScanKey keys,
         int nkeys,
         ScanKey orderbys,
         int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, `NULL` is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambeginscan`. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```
boolean
amgettuple (IndexScanDesc scan,
           ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns `TRUE` if a tuple was obtained, `FALSE` if no matching tuples remain. In the `TRUE` case the tuple TID is stored into the `scan` structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test. On success, `amgettuple` must also set `scan->xs_recheck` to `TRUE` or `FALSE`. `FALSE` means it is certain that the index entry matches the scan keys. `TRUE` means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by `amgettuple` callers.

If the index supports index-only scans (i.e., `amcanreturn` returns `TRUE` for it), then on success the AM must also check `scan->xs_want_itup`, and if that is true it must return the originally indexed data for the index entry. The data can be returned in the form of an `IndexTuple` pointer stored at `scan->xs_itup`, with tuple descriptor `scan->xs_itupdesc`; or in the form of a `HeapTuple` pointer stored at `scan->xs_hitup`, with tuple descriptor `scan->xs_hitupdesc`. (The latter format should be used when reconstructing data that might possibly not fit into an `IndexTuple`.) In either case, management of the data referenced by the pointer is the access method's responsibility. The data must remain good at least until the next `amgettuple`, `amrescan`, or `amendscan` call for the scan.

The `amgettuple` function need only be provided if the access method supports “plain” index scans. If it doesn't, the `amgettuple` field in its `IndexAmRoutine` struct must be set to `NULL`.

```
int64
amgetbitmap (IndexScanDesc scan,
```

```
TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied `TIDBitmap` (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, `amgetbitmap` can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the `xs_recheck` output parameter of `amgettupple`. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. `amgetbitmap` and `amgettupple` cannot be used in the same index scan; there are other restrictions too when using `amgetbitmap`, as explained in Section 61.3.

The `amgetbitmap` function need only be provided if the access method supports “bitmap” index scans. If it doesn't, the `amgetbitmap` field in its `IndexAmRoutine` struct must be set to `NULL`.

```
void  
amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released.

```
void  
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

The `ammarkpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `ammarkpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

```
void  
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

The `amrestrpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `amrestrpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

In addition to supporting ordinary index scans, some types of index may wish to support *parallel index scans*, which allow multiple backends to cooperate in performing an index scan. The index access method should arrange things so that each cooperating process returns a subset of the tuples that would be performed by an ordinary, non-parallel index scan, but in such a way that the union of those subsets is equal to the set of tuples that would be returned by an ordinary, non-parallel index scan. Furthermore, while there need not be any global ordering of tuples returned by a parallel scan, the ordering of that subset of tuples returned within each cooperating backend must match the requested ordering. The following functions may be implemented to support parallel index scans:

```
Size  
amestimateparallelscale (void);
```

Estimate and return the number of bytes of dynamic shared memory which the access method will be needed to perform a parallel scan. (This number is in addition to, not in lieu of, the amount of space needed for AM-independent data in `ParallelIndexScanDescData`.)

It is not necessary to implement this function for access methods which do not support parallel scans or for which the number of additional bytes of storage required is zero.

```
void  
aminitalizeparallelscale (void *target);
```

This function will be called to initialize dynamic shared memory at the beginning of a parallel scan. `target` will point to at least the number of bytes previously returned by `amestimateparallelscale`, and this function may use that amount of space to store whatever data it wishes.

It is not necessary to implement this function for access methods which do not support parallel scans or in cases where the shared memory space required needs no initialization.

```
void  
amparallelrescan (IndexScanDesc scan);
```

This function, if implemented, will be called when a parallel index scan must be restarted. It should reset any shared state set up by `aminitparallelscan` such that the scan will be restarted from the beginning.

## 61.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the *scan keys*. The access method is *not* involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's time qualification test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form *index\_key operator constant*, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.
- Access methods that support ordering operators should set `amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettuple` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettuple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettuple` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans need not provide `ammarkpos` and `amrestrpos` functions in `IndexAmRoutine`; set those pointers to NULL instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support index-only scans, in which the index returns the actual data not just the TID of the heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method's.

Instead of using `amgettuple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettuple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettuple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn't supported. Secondly, the tuples are returned in a bitmap which doesn't have any specific ordering, which is why `amgetbitmap` doesn't take a `direction` argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in Section 61.4.

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettuple`, or vice versa, if its internal implementation is unsuited to one API or the other.

## 61.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An exclusive lock on the index as a whole will be taken only during index creation, destruction, or `REINDEX`.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior. For the b-tree and hash index types, you can read about the design decisions involved in `src/backend/access/nbtree/README` and `src/backend/access/hash/README`.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 61.5.)
- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because

the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

## 61.5. Index Uniqueness Checks

enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns which are present in the `INCLUDE` clause are not used to enforce uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it's okay. (In particular, since an `UPDATE` always deletes the old row version before inserting the new version, this will allow an `UPDATE` on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that's just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate

probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row's index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, "live" actually means "any tuple in the index entry's HOT chain is live".) To implement this, the `aminsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. will use this mode to insert each row's index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning `FALSE` from `aminsert`. For each row for which `FALSE` is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must *not* insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

## 61.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of `WHERE` and `ORDER BY` clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the `WHERE` clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```
void
amcostestimate (PlannerInfo *root,
               IndexPath *path,
               double loop_count,
               Cost *indexStartupCost,
               Cost *indexTotalCost,
```

## Index Access Method Interface Definition

---

```
Selectivity *indexSelectivity,  
double *indexCorrelation);
```

The first three parameters are inputs:

*root*

The planner's information about the query being processed.

*path*

The index access path being considered. All fields except cost and selectivity values are valid.

*loop\_count*

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger *loop\_count* means that it may be appropriate to allow for some caching effects across multiple scans.

The last four parameters are pass-by-reference outputs:

*\*indexStartupCost*

Set to cost of index start-up processing

*\*indexTotalCost*

Set to total cost of index processing

*\*indexSelectivity*

Set to index selectivity

*\*indexCorrelation*

Set to correlation coefficient between index scan order and underlying table's order

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by `src/backend/optimizer/path/costsize.c`: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of `cpu_operator_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but *not* the costs of retrieving or processing the parent-table rows that are identified by the index.

The "start-up cost" is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The *indexSelectivity* should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The *indexCorrelation* should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

When *loop\_count* is greater than one, the returned numbers should be averages expected for any one scan of the index.

## Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:

```
*indexSelectivity = clauselist_selectivity(root, path->indexquals,  
                                           path->indexinfo->rel->relid,  
                                           JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as `indexSelectivity` times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the `path->indexinfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just `indexSelectivity` times the index's size in pages.
4. Compute the index access cost. A generic estimator might do this:

```
/*  
 * Our generic assumption is that the index pages will be read  
 * sequentially, so they cost seq_page_cost each, not random_page_cost.  
 * Also, we charge for evaluation of the indexquals at each index row.  
 * All the costs are assumed to be paid incrementally during the scan.  
 */  
cost_qual_eval(&index_qual_cost, path->indexquals, root);  
*indexStartupCost = index_qual_cost.startup;  
*indexTotalCost = seq_page_cost * numIndexPages +  
                  (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in `src/backend/utils/adt/selfuncs.c`.

---

## Chapter 62. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way. This is useful for extensions that provide custom access methods, because they cannot register their own WAL redo routines.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.
2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer's contents directly.) The third argument is a bit mask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.
3. Apply modifications to the page images obtained in the previous step.
4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller's responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.
- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.
- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.
- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.
- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.
- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.
- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.
- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.
- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte compar-

ison. This is not very compact for the case of moving data within a page, and might be improved in the future.

---

# Chapter 63. GiST Indexes

## 63.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project *web site* and Marcel Kornacker's thesis, *Access Methods for Next-Generation Database Systems*. The GiST implementation in is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their *web site*.

## 63.2. Built-in Operator Classes

The core distribution includes the GiST operator classes shown in Table 63.1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

**Table 63.1. Built-in GiST Operator Classes**

Name	Indexed Data Type	Indexable Operators	Ordering Operators
box_ops	box	&& &> &< &<  >> << <<  <@ @> @  &>  >> ~ ~=	
circle_ops	circle	&& &> &< &<  >> << <<  <@ @> @  &>  >> ~ ~=	<->
inet_ops	inet, cidr	&& >> >>= > >= <> << <<= < <= =	
point_ops	point	>> >^ << <@ <@ <@ <^ ~= ~>	<->
poly_ops	polygon	&& &> &< &<  >> << <<  <@ @> @  &>  >> ~ ~=	<->
range_ops	any range type	&& &> &< >> << <@ - - = @> @>	
tsquery_ops	tsquery	<@ @>	
tsvector_ops	tsvector	@@	

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

## 63.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, supports extensible B-trees and hash indexes. That means that you can use to build a B-tree or hash over any data type you want. But B-trees only support range predicates (<, =, >), and hash indexes only support equality queries.

So if you index, say, an image collection with a B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they're relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are seven methods that an index operator class for GiST must provide, and two that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. The remaining two basic methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow data type rules here, see about `varlena` for variable sized data). If the tree's internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans.

`consistent`

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match. In that case the system will automatically evaluate the `indexable_operator` against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid,
    internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataTypes(entry->key);
    bool retval;

    /*
     * determine return value as a function of strategy, key and query.
    */
}
```

```

*
* Use GIST_LEAF(entry) to know where you're called in the index tree,
* which comes handy when supporting the = operator for example (you could
* check for non empty union() in non-leaf nodes and equality in leaf
* nodes).
*/

*recheck = true;          /* or false if check is exact */

PG_RETURN_BOOL(retval);
}

```

Here, `key` is an element in the index and `query` the value being looked up in the index. The `StrategyNumber` parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command.

Depending on which operators you have included in the class, the data type of `query` could vary with the operator, since it will be whatever type is on the righthand side of the operator, which might be different from the indexed data type appearing on the lefthand side. (The above code skeleton assumes that only one type is possible; if not, fetching the `query` argument value would have to depend on the operator.) It is recommended that the SQL declaration of the `consistent` function use the `opclass`'s indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

`union`

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
              *tmp,
              *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }
}

```

```

for (i = 1; i < numranges; i++)
{
    old = out;
    tmp = DatumGetDataTypes(ent[i].key);
    out = my_union_implementation(out, tmp);
}

PG_RETURN_DATA_TYPE_P(out);
}

```

As you can see, in this skeleton we're dealing with a data type where  $\text{union}(X, Y, Z) = \text{union}(\text{union}(X, Y), Z)$ . It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the union function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The union function should return a pointer to newly `palloc()`ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the union function's first internal argument is actually a `GistEntryVector` pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the union function store the size of its result value into that variable, but this is no longer necessary.)

`compress`

Converts the data item into a format suitable for physical storage in an index page.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data =
palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */

        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                    entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {

```

```

        /* typically we needn't do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}

```

You have to adapt *compressed\_data\_type* to the specific type you're converting to in order to compress your leaf nodes, of course.

#### decompress

The reverse of the *compress* method. Converts the index representation of the data item into a format that can be manipulated by the other GiST methods in the operator class.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}

```

The above skeleton is suitable for the case where no decompression is needed.

#### penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least *penalty* in the tree. Values returned by *penalty* should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataTypes(origentry->key);
    data_type *new = DatumGetDataTypes(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}

```

```
}

```

For historical reasons, the `penalty` function doesn't just return a `float` result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The `penalty` function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

`picksplit`

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
    data_type *unionL;
    data_type *unionR;
    GISTENTRY **raw_entryvec;

    maxoff = entryvec->n - 1;
    nbytes = (maxoff + 1) * sizeof(OffsetNumber);

    v->spl_left = (OffsetNumber *) palloc(nbytes);
    left = v->spl_left;
    v->spl_nleft = 0;

    v->spl_right = (OffsetNumber *) palloc(nbytes);
    right = v->spl_right;
    v->spl_nright = 0;

    unionL = NULL;
    unionR = NULL;

    /* Initialize the raw entry vector. */
    raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
    for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
        raw_entryvec[i] = &(entryvec->vector[i]);
}
```

```

for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
{
    int            real_index = raw_entryvec[i] - entryvec->vector;

    tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
    Assert(tmp_union != NULL);

    /*
     * Choose where to put the index entries and update unionL and unionR
     * accordingly. Append the entries to either v_spl_left or
     * v_spl_right, and care about the counters.
     */

    if (my_choice_is_left(unionL, curl, unionR, curr))
    {
        if (unionL == NULL)
            unionL = tmp_union;
        else
            unionL = my_union_implementation(unionL, tmp_union);

        *left = real_index;
        ++left;
        ++(v->spl_nleft);
    }
    else
    {
        /*
         * Same on the right
         */
    }
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
}

```

Notice that the `picksplit` function's result is delivered by modifying the passed-in `v` structure. The return value per se is ignored, though it's conventional to pass back the address of `v`.

Like `penalty`, the `picksplit` function is crucial to good performance of the index. Designing suitable `penalty` and `picksplit` implementations is where the challenge of implementing well-performing GiST indexes lies.

same

Returns true if two index entries are identical, false otherwise. (An "index entry" is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_same);
```

```
Datum
```

```

my_same (PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool          *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}

```

For historical reasons, the `same` function doesn't just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

`distance`

Given an index entry `p` and a query value `q`, this function determines the index entry's "distance" from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest "distance" values first, so the results must be consistent with the operator's semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```

CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;

```

And the matching code in the C module could then follow this skeleton:

```

PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance (PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
    data_type *key = DatumGetDataTypes(entry->key);
    double     retval;

    /*
     * determine return value as a function of strategy, key and query.
     */

    PG_RETURN_FLOAT8(retval);
}

```

The arguments to the `distance` function are identical to the arguments of the `consistent` function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set `*recheck` to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns `*recheck = true` for any leaf node, the original ordering operator's return type must be `float8` or `float4`, and the distance function's result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite `float8` values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that distance functions return these values.)

`fetch`

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `GISTENTRY` struct. On entry, its `key` field contains a non-NULL leaf datum in compressed form. The return value is another `GISTENTRY` struct, whose `key` field contains the same datum in its original, uncompressed form. If the opclass's compress function does nothing for leaf entries, the `fetch` method can return the argument as-is.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);

Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetP(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original datatype.
     */

    /* fill *retval from fetched_data. */
    gistentryinit(retval, PointerGetDatum(converted_datum),
                  entry->rel, entry->page, entry->offset, FALSE);

    PG_RETURN_POINTER(retval);
}
```

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a `fetch` function.

All the GiST support methods are normally called in short-lived memory contexts; that is, `CurrentMemoryContext` will get reset after each tuple is processed. It is therefore not very important to worry about `pfree`'ing everything you `palloc`. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in `fcinfo->flinfo->fn_mcxt`, and keep a pointer to it in `fcinfo->flinfo->fn_extra`. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to `pfree` the previous value when replacing a `fn_extra` value, or the leak will accumulate for the duration of the operation.

## 63.4. Implementation

### 63.4.1. GiST buffering build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, the insertions need to perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole does not.

However, buffering index build needs to call the `penalty` function more often, which consumes some extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches `effective_cache_size`. It can be manually turned on or off by the `buffering` parameter to the `CREATE INDEX` command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

## 63.5. Examples

The source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for `tsvector` and `tsquery`) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see `src/backend/access/gist/gistproc.c`). The following `contrib` modules also contain GiST operator classes:

`btree_gist`

B-tree equivalent functionality for several data types

`cube`

Indexing for multidimensional cubes

`hstore`

Module for storing (key, value) pairs

`intarray`

RD-Tree for one-dimensional array of int4 values

`ltree`

Indexing for tree-like structures

`pg_trgm`

Text similarity using trigram matching

`seg`

Indexing for “float ranges”

---

# Chapter 64. SP-GiST Indexes

## 64.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University's SP-GiST Indexing Project *web site*. The SP-GiST implementation is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their *web site*.

## 64.2. Built-in Operator Classes

The core distribution includes the SP-GiST operator classes shown in Table 64.1.

**Table 64.1. Built-in SP-GiST Operator Classes**

Name	Indexed Data Type	Indexable Operators
kd_point_ops	point	<< <@ <^ >> >^ ~=
quad_point_ops	point	<< <@ <^ >> >^ ~=
range_ops	any range type	&& &< &> - - << <@ = >> @>
box_ops	box	<< &< && &> >> ~= @> <@ &<  <<    >>  &>
text_ops	text	< <= = > >= ~<=~ ~<~ ~>=~ ~>~
inet_ops	inet, cidr	&& >> >>= > >= <> << <<= < <= =

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure which may offer better performance in some applications.

## 64.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more *nodes*, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a *label* that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels, if it works with a fixed set of nodes for all inner tuples; see Section 64.4.2.) Optionally, an inner tuple can have a *prefix* value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called *traverse values*) during a tree descent.

### Note

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide. All five follow the convention of accepting two `internal` arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the methods just return `void`, since all their results appear in the output struct; but `leaf_consistent` additionally returns a `boolean` result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method.

The five user-defined methods are:

`config`

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgConfigIn` C struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` C struct, which the function must fill with result data.

```
typedef struct spgConfigIn
{
    Oid          attType;          /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut
{
    Oid          prefixType;       /* Data type of inner-tuple prefixes */
    Oid          labelType;       /* Data type of inner-tuple node labels */
    bool         canReturnData;    /* Opclass can reconstruct original data */
    bool         longValuesOK;    /* Opclass can cope with values > 1 page */
}
```

```
} spgConfigOut;
```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 64.4.1).

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgChooseIn` C struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` C struct, which the function must fill with result data.

```
typedef struct spgChooseIn
{
    Datum        datum;           /* original datum to be indexed */
    Datum        leafDatum;       /* current datum to be stored at leaf */
    int          level;          /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool         allTheSame;      /* tuple is marked all-the-same? */
    bool         hasPrefix;      /* tuple has a prefix? */
    Datum        prefixDatum;     /* if so, the prefix value */
    int          nNodes;         /* number of nodes in the inner tuple */
    Datum        *nodeLabels;     /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1,           /* descend into existing node */
    spgAddNode,                 /* add a node to the inner tuple */
    spgSplitTuple               /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see above */
    union
    {
        struct                /* results for spgMatchNode */
        {
            int                nodeN; /* descend to this node (index from 0) */
            int                levelAdd; /* increment level by this much */
            Datum              restDatum; /* new leaf datum */
        } matchNode;
        struct                /* results for spgAddNode */
        {
            Datum              nodeLabel; /* new node's label */
            int                nodeN; /* where to insert it (index from 0) */
        } addNode;
        struct                /* results for spgSplitTuple */
```

```

{
    /* Info to form new upper-level inner tuple with one child tuple */
    bool        prefixHasPrefix; /* tuple should have a prefix? */
    Datum       prefixPrefixDatum; /* if so, its value */
    int         prefixNNodes; /* number of nodes */
    Datum       *prefixNodeLabels; /* their labels (or NULL for
    * no labels) */
    int         childNodeN; /* which node gets child tuple */

    /* Info to form new lower-level inner tuple with all old nodes */
    bool        postfixHasPrefix; /* tuple should have a prefix? */
    Datum       postfixPrefixDatum; /* if so, its value */
    }          splitTuple;
}          result;
} spgChooseOut;

```

`datum` is the original datum that was to be inserted into the index. `leafDatum` is initially the same as `datum`, but can change at lower levels of the tree if the `choose` or `picksplit` methods change it. When the insertion search reaches a leaf page, the current value of `leafDatum` is what will be stored in the newly created leaf tuple. `level` is the current inner tuple's level, starting at zero for the root level. `allTheSame` is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 64.4.3). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if there are no labels.

The `choose` function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set `resultType` to `spgMatchNode`. Set `nodeN` to the index (from zero) of that node in the node array. Set `levelAdd` to the increment in `level` caused by descending through that node, or leave it as zero if the operator class does not use levels. Set `restDatum` to equal `datum` if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as `leafDatum` at the next level.

If a new child node must be added, set `resultType` to `spgAddNode`. Set `nodeLabel` to the label to be used for the new node, and set `nodeN` to the index (from zero) at which to insert the node in the node array. After the node has been added, the `choose` function will be called again with the modified inner tuple; that call should result in an `spgMatchNode` result.

If the new value is inconsistent with the tuple prefix, set `resultType` to `spgSplitTuple`. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single downlink pointing to the new lower-level inner tuple. Set `prefixHasPrefix` to indicate whether the new upper tuple should have a prefix, and if so set `prefixPrefixDatum` to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed. Set `prefixNNodes` to the number of nodes needed in the new tuple, and set `prefixNodeLabels` to a `palloc'd` array holding their labels, or to NULL if node labels are not required. Note that the total size of the new upper tuple must be no more than the total size of the tuple it is replacing; this constrains the lengths of the new prefix and new labels. Set `childNodeN` to the index (from zero) of the node that will downlink to the new lower-level inner tuple. Set `postfixHasPrefix` to indicate whether the new lower-level inner tuple should have a prefix, and if so set `postfixPrefixDatum` to the prefix value. The combination of these two prefixes and the downlink node's label (if any) must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the `choose` function will be called again with the replacement inner tuple. That call may return an `spgAddNode` result, if no suitable node was created by the `spgSplitTuple` action. Eventually `choose` must return `spgMatchNode` to allow the insertion to descend to the next level.

`picksplit`

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```
typedef struct spgPickSplitIn
{
    int          nTuples;          /* number of leaf tuples */
    Datum        *datums;          /* their datums (array of length nTuples) */
    int          level;           /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool         hasPrefix;        /* new inner tuple should have a prefix? */
    Datum        prefixDatum;     /* if so, its value */

    int          nNodes;          /* number of nodes for new inner tuple */
    Datum        *nodeLabels;     /* their labels (or NULL for no labels) */

    int          *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum        *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values, or to NULL if node labels are not required. Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for `palloc`'ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See Section 64.4.3 for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `long-ValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See Section 64.4.1 for more information.

`inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgInnerConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    int          nkeys;            /* length of array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue; /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext; /* put new traverse values here */
    int          level;            /* current level (counting from zero) */
    bool         returnData;       /* original data must be returned? */

    /* Data from current inner tuple */
    bool         allTheSame;       /* tuple is marked all-the-same? */
    bool         hasPrefix;       /* tuple has a prefix? */
    Datum        prefixDatum;     /* if so, the prefix value */
    int          nNodes;          /* number of nodes in the inner tuple */
    Datum        *nodeLabels;     /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int          nNodes;          /* number of child nodes to be visited */
    int          *nodeNumbers;    /* their indexes in the node array */
    int          *levelAdds;      /* increment level by this much for each */
    Datum        *reconstructedValues; /* associated reconstructed values */
    void         **traversalValues; /* opclass-specific traverse values */
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. `reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `traversalMemoryContext` is the memory context in which to store output traverse values (see below). `level` is the current inner tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 64.4.3). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search,

set `traversalValues` to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave `traversalValues` as `NULL`. Note that the `inner_consistent` function is responsible for `palloc`'ing the `nodeNumbers`, `levelAdds`, `reconstructedValues`, and `traversalValues` arrays in the current memory context. However, any output traverse values pointed to by the `traversalValues` array should be allocated in `traversalMemoryContext`. Each traverse value must be a single `palloc`'d chunk.

`leaf_consistent`

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgLeafConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    int          nkeys;             /* length of array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue;    /* opclass-specific traverse value */
    int          level;             /* current level (counting from zero) */
    bool         returnData;        /* original data must be returned? */

    Datum        leafDatum;         /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum        leafValue;         /* reconstructed original data, if any */
    bool         recheck;          /* set true if operator must be rechecked */
} spgLeafConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is `NULL`, because the SP-GiST core code will filter out such conditions. `reconstructedValue` is the value reconstructed for the parent tuple; it is `(Datum) 0` at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or `NULL` at the root level. `level` is the current leaf tuple's level, starting at zero for the root level. `returnData` is `true` if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value stored in the current leaf tuple.

The function must return `true` if the leaf tuple matches the query, or `false` if not. In the `true` case, if `returnData` is `true` then `leafValue` must be set to the value originally supplied to be indexed for this leaf tuple. Also, `recheck` may be set to `true` if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about `pfree`'ing everything you `palloc`. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

## 64.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

### 64.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to `TRUE` only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple *must* divide the set of leaf values into more than one node group. If the operator class's `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 64.4.3.

### 64.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return `NULL` for the `nodeLabels` array, and likewise the `choose` function can return `NULL` for the `prefixNodeLabels` array during a `spgSplitTuple` action. This will in turn result in `nodeLabels` being `NULL` during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases.

### 64.4.3. “All-the-same” Inner Tuples

The SP-GiST core can override the results of the operator class's `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn't match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may

not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

## 64.5. Examples

The source distribution includes several examples of index operator classes for SP-GiST, as described in Table 64.1. Look into `src/backend/access/spgist/` and `src/backend/utils/adt/` to see the code.

# Chapter 65. GIN Indexes

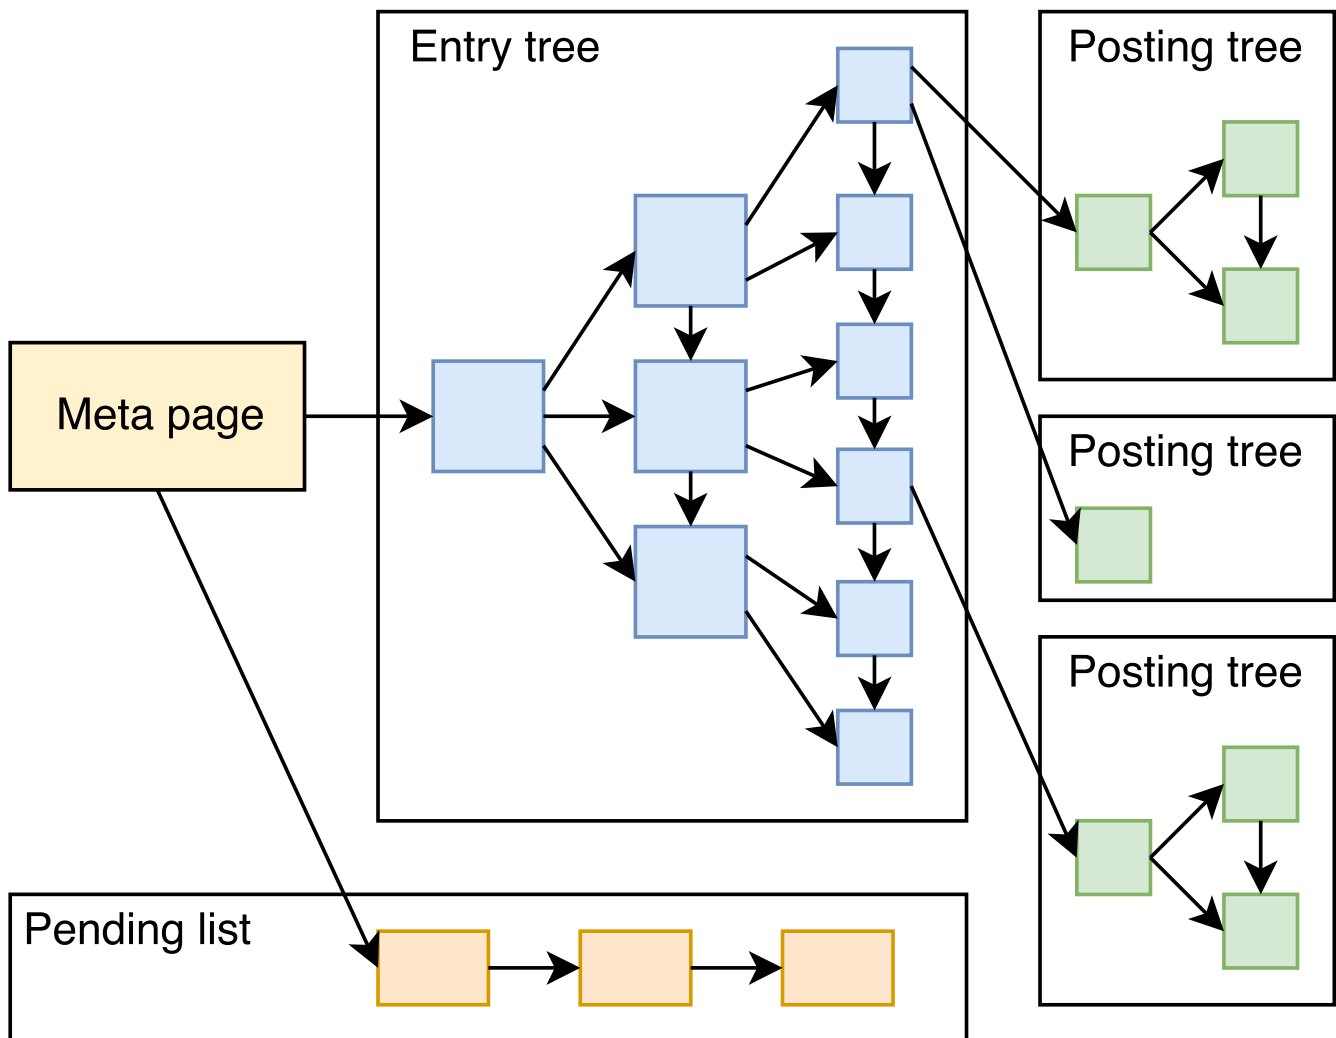

## 65.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

Figure 65.1. GIN index

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their *website*.

## 65.2. Built-in Operator Classes

The core distribution includes the GIN operator classes shown in Table 65.1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

**Table 65.1. Built-in GIN Operator Classes**

Name	Indexed Data Type	Indexable Operators
array_ops	anyarray	&& <@ = @>
jsonb_ops	jsonb	? ?& ?  @>
jsonb_path_ops	jsonb	@>
tsvector_ops	tsvector	@@ @@@

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

## 65.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

```
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the item contains no keys.

```
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer
**extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc'd array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see Section 38.14.2). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the `query` contains no keys.

`searchMode` is an output argument that allows `extractQuery` to specify details about how the search will be done. If `*searchMode` is set to `GIN_SEARCH_MODE_DEFAULT` (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If `*searchMode` is set to `GIN_SEARCH_MODE_INCLUDE_EMPTY`, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate match-

es. (This mode is useful for implementing is-subset-of operators, for example.) If `*searchMode` is set to `GIN_SEARCH_MODE_ALL`, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

`pmatch` is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of `*nkeys` booleans and store its address at `*pmatch`. Each element of the array should be set to `TRUE` if the corresponding key requires partial match, `FALSE` if not. If `*pmatch` is set to `NULL` then GIN assumes partial match is not required. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not support partial match.

`extra_data` is an output argument that allows `extractQuery` to pass additional data to the `consistent` and `comparePartial` methods. To use it, `extractQuery` must allocate an array of `*nkeys` pointers and store its address at `*extra_data`, then store whatever it wants to into the individual pointers. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not require extra data. If `*extra_data` is set, the whole array is passed to the `consistent` method, and the appropriate element to the `comparePartial` method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a boolean `consistent` function, and a ternary `triConsistent` function. `triConsistent` covers the functionality of both, so providing `triConsistent` alone is sufficient. However, if the boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns `TRUE` if an indexed item satisfies the query operator with strategy number `n` (or might satisfy it, if the `recheck` indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The `check` array has length `nkeys`, which is the same as the number of keys previously returned by `extractQuery` for this query datum. Each element of the `check` array is `TRUE` if the indexed item contains the corresponding query key, i.e., if `(check[i] == TRUE)` the `i`-th key of the `extractQuery` result array is present in the indexed item. The original query datum is passed in case the `consistent` method needs to consult it, and so are the `queryKeys[]` and `nullFlags[]` arrays previously returned by `extractQuery`. `extra_data` is the extra-data array returned by `extractQuery`, or `NULL` if none.

When `extractQuery` returns a null key in `queryKeys[]`, the corresponding `check[]` element is `TRUE` if the indexed item contains a null key; that is, the semantics of `check[]` are like `IS NOT DISTINCT FROM`. The `consistent` function can examine the corresponding `nullFlags[]` element if it needs to tell the difference between a regular value match and a null match.

On success, `*recheck` should be set to `TRUE` if the heap tuple needs to be rechecked against the query operator, or `FALSE` if the index test is exact. That is, a `FALSE` return value guarantees that the heap tuple does not match the query; a `TRUE` return value with `*recheck` set to `FALSE` guarantees that the heap tuple does match the query; and a `TRUE` return value with `*recheck` set to `TRUE` means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

`triConsistent` is similar to `consistent`, but instead of booleans in the `check` vector, there are three possible values for each key: `GIN_TRUE`, `GIN_FALSE` and `GIN_MAYBE`. `GIN_FALSE` and `GIN_TRUE` have the same meaning as regular boolean values, while `GIN_MAYBE` means that the presence of that key is not known. When `GIN_MAYBE` values are present, the function should only return `GIN_TRUE` if the item

certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return `GIN_FALSE` only if the item certainly does not match, whether or not it contains the `GIN_MAYBE` keys. If the result depends on the `GIN_MAYBE` entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return `GIN_MAYBE`.

When there are no `GIN_MAYBE` values in the `check` vector, a `GIN_MAYBE` return value is the equivalent of setting the `recheck` flag in the boolean `consistent` function.

In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default `btree` operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the `btree` operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

Optionally, an operator class for GIN can supply the following method:

```
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See Section 65.4.2 for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the `opclass`'s indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

## 65.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

### 65.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when `gin_clean_pending_list` function is called, or if the pending list becomes larger than `gin_pending_list_limit`, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See `CREATE INDEX` for details.

### 65.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

## 65.5. GIN Tips and Tricks

#### Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see Section 65.4.1 for details). But for very large updates it may still be best to drop and recreate the index.

#### `maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

#### `gin_pending_list_limit`

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, and which allows each GIN index to have its own cleanup threshold. For example, it's possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

### `gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in , and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system's random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

## 65.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

## 65.7. Examples

The core distribution includes the GIN operator classes previously shown in Table 65.1. The following `contrib` modules also contain GIN operator classes:

`btree_gin`

B-tree equivalent functionality for several data types

`hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int[]`

`pg_trgm`

Text similarity using trigram matching

---

# Chapter 66. BRIN Indexes

## 66.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table. A *block range* is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is *consistent* with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

### 66.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, that range does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating initial summaries. This process can be invoked manually using the `brin_summarize_range(regclass, bigint)` or `brin_summarize_new_values(regclass)` functions; automatically when `VACUUM` processes the table; or by automatic summarization executed by `autovacuum`, as insertions occur. (This last trigger is disabled by default and can be enabled with the `autosummarize` parameter.) Conversely, a range can be de-summarized using the `brin_desummarize_range(regclass, bigint)` function, which is useful when the index tuple is no longer a very good representation because the existing values have changed.

## 66.2. Built-in Operator Classes

The core distribution includes the BRIN operator classes shown in Table 66.1.

The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range.

**Table 66.1. Built-in BRIN Operator Classes**

Name	Indexed Data Type	Indexable Operators
<code>abstime_minmax_ops</code>	<code>abstime</code>	<code>&lt; &lt;= = &gt;= &gt;</code>
<code>int8_minmax_ops</code>	<code>bigint</code>	<code>&lt; &lt;= = &gt;= &gt;</code>
<code>bit_minmax_ops</code>	<code>bit</code>	<code>&lt; &lt;= = &gt;= &gt;</code>

Name	Indexed Data Type	Indexable Operators
varbit_minmax_ops	bit varying	< <= = >= >
box_inclusion_ops	box	<< &< && &> >> ~ = @ > <@ &<  <<    >>  &>
bytea_minmax_ops	bytea	< <= = >= >

timestamp_minmax_ops	timestamp without time zone	< <= = >= >
timestamptz_minmax_ops	timestamp with time zone	< <= = >= >
time_minmax_ops	time without time zone	< <= = >= >
timetz_minmax_ops	time with time zone	< <= = >= >
uuid_minmax_ops	uuid	< <= = >= >

## 66.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

```
BrinOpcInfo *opcInfo(Oid type_oid)
```

Returns internal information about the indexed columns' summary data. The return value must point to a `malloc'd` `BrinOpcInfo`, which has this definition:

```

typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this opclass */
    uint16      oi_nstored;

    /* Opaque pointer for the opclass' private use */
    void        *oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;

```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support procedures during an index scan.

```
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)
```

Returns whether the `ScanKey` is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key.

```
bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)
```

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

```
bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)
```

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

The core distribution includes support for two types of operator classes: `minmax` and `inclusion`. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support procedures' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support procedures described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support procedures might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the `minmax` support procedures alongside the corresponding operators, as shown in Table 66.2. All operator class members (procedures and operators) are mandatory.

**Table 66.2. Procedure and Support Numbers for Minmax Operator Classes**

Operator class member	Object
Support Procedure 1	internal function <code>brin_minmax_opcinfo()</code>
Support Procedure 2	internal function <code>brin_minmax_add_value()</code>
Support Procedure 3	internal function <code>brin_minmax_consistent()</code>
Support Procedure 4	internal function <code>brin_minmax_union()</code>
Operator Strategy 1	operator <code>less-than</code>
Operator Strategy 2	operator <code>less-than-or-equal-to</code>
Operator Strategy 3	operator <code>equal-to</code>
Operator Strategy 4	operator <code>greater-than-or-equal-to</code>
Operator Strategy 5	operator <code>greater-than</code>

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support procedures alongside the corresponding operators, as shown in Table 66.3. It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

**Table 66.3. Procedure and Support Numbers for Inclusion Operator Classes**

Operator class member	Object	Dependency
Support Procedure 1	internal function <code>brin_inclusion_opcinfo()</code>	
Support Procedure 2	internal function <code>brin_inclusion_add_value()</code>	
Support Procedure 3	internal function <code>brin_inclusion_consistent()</code>	
Support Procedure 4	internal function <code>brin_inclusion_union()</code>	
Support Procedure 11	function to merge two elements	
Support Procedure 12	optional function to check whether two elements are mergeable	
Support Procedure 13	optional function to check if an element is contained within another	
Support Procedure 14	optional function to check whether an element is empty	
Operator Strategy 1	operator left-of	Operator Strategy 4
Operator Strategy 2	operator does-not-extend-to-the-right-of	Operator Strategy 5
Operator Strategy 3	operator overlaps	
Operator Strategy 4	operator does-not-extend-to-the-left-of	Operator Strategy 1
Operator Strategy 5	operator right-of	Operator Strategy 2
Operator Strategy 6, 18	operator same-as-or-equal-to	Operator Strategy 7
Operator Strategy 7, 13, 16, 24, 25	operator contains-or-equal-to	
Operator Strategy 8, 14, 26, 27	operator is-contained-by-or-equal-to	Operator Strategy 3
Operator Strategy 9	operator does-not-extend-above	Operator Strategy 11
Operator Strategy 10	operator is-below	Operator Strategy 12
Operator Strategy 11	operator is-above	Operator Strategy 9
Operator Strategy 12	operator does-not-extend-below	Operator Strategy 10
Operator Strategy 20	operator less-than	Operator Strategy 5
Operator Strategy 21	operator less-than-or-equal-to	Operator Strategy 5
Operator Strategy 22	operator greater-than	Operator Strategy 1
Operator Strategy 23	operator greater-than-or-equal-to	Operator Strategy 1

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of

them. The inclusion operator class can store union values with different data types if it is defined with the `STORAGE` parameter. The return value of the union function should match the `STORAGE` data type.

Support procedure numbers 12 and 14 are provided to support irregularities of built-in data types. Procedure number 12 is used to support network addresses from different families which are not mergeable. Procedure number 14 is used to support empty ranges. Procedure number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in Table 66.3, or the same operator strategy as themselves. They require the dependency operator to be defined with the `STORAGE` data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See `float4_minmax_ops` as an example of minmax, and `box_inclusion_ops` as an example of inclusion.

---

# Chapter 67. Database Physical Storage

This chapter provides an overview of the physical storage format used by databases.

## 67.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster's data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in Table 67.1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

**Table 67.1. Contents of `PGDATA`**

Item	Description
<code>PG_VERSION</code>	A file containing the major version number of
<code>base</code>	Subdirectory containing per-database subdirectories
<code>current_logfiles</code>	File recording the log file(s) currently written to by the logging collector
<code>global</code>	Subdirectory containing cluster-wide tables, such as <code>pg_database</code>
<code>pg_commit_ts</code>	Subdirectory containing transaction commit timestamp data
<code>pg_dynshmem</code>	Subdirectory containing files used by the dynamic shared memory subsystem
<code>pg_logical</code>	Subdirectory containing status data for logical decoding
<code>pg_multixact</code>	Subdirectory containing multitransaction status data (used for shared row locks)
<code>pg_notify</code>	Subdirectory containing LISTEN/NOTIFY status data
<code>pg_replslot</code>	Subdirectory containing replication slot data
<code>pg_serial</code>	Subdirectory containing information about committed serializable transactions
<code>pg_snapshots</code>	Subdirectory containing exported snapshots
<code>pg_stat</code>	Subdirectory containing permanent files for the statistics subsystem
<code>pg_stat_tmp</code>	Subdirectory containing temporary files for the statistics subsystem
<code>pg_subtrans</code>	Subdirectory containing subtransaction status data
<code>pg_tblspc</code>	Subdirectory containing symbolic links to tablespaces
<code>pg_twophase</code>	Subdirectory containing state files for prepared transactions
<code>pg_wal</code>	Subdirectory containing WAL (Write Ahead Log) files

Item	Description
pg_xact	Subdirectory containing transaction commit status data
postgresql.auto.conf	A file used for storing configuration parameters that are set by <code>ALTER SYSTEM</code>
postmaster.opts	A file recording the command-line options the server was last started with
postmaster.pid	A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (empty on Windows), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database's OID in `pg_database`. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's *filenode* number, which can be found in `pg_class.relfilenode`. But for temporary relations, the file name is of the form `tBBB_FFF`, where *BBB* is the backend ID of the backend which created the file, and *FFF* is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a *free space map* (see Section 67.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix `_fsm`. Tables also have a *visibility map*, stored in a fork with the suffix `_vm`, to track which pages are known to have no dead tuples. The visibility map is described further in Section 67.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix `_init` (see Section 67.5).

### Caution

Note that while a table's filenode often matches its OID, this is *not* necessarily the case; some operations, like `TRUNCATE`, `REINDEX`, `CLUSTER` and some forms of `ALTER TABLE`, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including `pg_class` itself, `pg_class.relfilenode` contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the `pg_relation_filenode()` function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the filenode; subsequent segments are named `filenode.1`, `filenode.2`, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option `--with-segsize` when building .) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. `pg_class.reltoastrelid` links from a table to its TOAST table, if any. See Section 67.2 for more information.

The contents of tables and indexes are discussed further in Section 67.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's `CREATE TABLESPACE` command). This symbolic link is named after

the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the server version, such as `PG_9.0_201008051`. (The reason for using this subdirectory is so that successive versions of the database can use the same `CREATE TABLESPACE` location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

The `pg_relation_filepath()` function shows the entire path (relative to `PGDATA`) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or `_fsm`, `_vm`, or `_init` to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmpPPP-P.NNN`, where `PPP` is the PID of the owning backend and `NNN` distinguishes different temporary files of that backend.

## 67.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called *TOASTed values* work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been *detoasted*. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible. See Section 38.11.1 for more detail.)

TOAST usurps two bits of the *varlena* length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ( $2^{30}$  - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a *TOAST pointer* are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the

total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a *TOAST table* that is separate from, but associated with, the table containing the TOAST pointer datum itself. These *on-disk* pointer datums are created by the TOAST management code (in `access/heap/tuptoaster.c`) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 67.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 67.2.2.

The compression technique used for either in-line or out-of-line compressed data is a fairly simple and very fast member of the LZ family of compression techniques. See `src/common/pg_lzcompress.c` for the details.

### 67.2.1. Out-of-line, on-disk TOAST storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and physical stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- `PLAIN` prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
- `EXTENDED` allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- `EXTERNAL` allows out-of-line storage but not compression. Use of `EXTERNAL` will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- `MAIN` allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

### 67.2.2. Out-of-line, in-memory TOAST storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of an array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the *N*'th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an "expanded" or "deconstructed" representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in `src/include/utils/expandeddatum.h`. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into *read-write* and *read-only* pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

## 67.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork,

named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See `src/backend/storage/freespace/README` for more details on how the FSM is structured, and how it's updated and searched. The `pg_freespacemap` module can be used to examine the information stored in free space maps.

## 67.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by *index-only scans* to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen. That means that even an anti-wraparound vacuum need not revisit the page.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The `pg_visibility` module can be used to examine the information stored in the visibility map.

## 67.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

## 67.6. Database Page Layout

This section provides an overview of the page format used within tables and indexes.<sup>1</sup> Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

---

<sup>1</sup> Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

Table 67.2 shows the overall layout of a page. There are five parts to each page.

**Table 67.2. Overall Page Layout**

Item	Description
PageHeaderData	24 bytes long. Contains general information about the page, including free space pointers.
ItemIdData	Array of (offset,length) pairs pointing to the actual items. 4 bytes per item.
Free space	The unallocated space. New item pointers are allocated from the start of this area, new items from the end.
Items	The actual items themselves.
Special space	Index access method specific data. Different methods store different data. Empty in ordinary tables.

The first 24 bytes of each page consists of a page header (`PageHeaderData`). Its format is detailed in Table 67.3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (`pd_lower`, `pd_upper`, and `pd_special`). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, `pd_pagesize_version`, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

**Table 67.3. PageHeaderData Layout**

Field	Type	Length	Description
<code>pd_lsn</code>	<code>PageXLogRecPtr</code>	8 bytes	LSN: next byte after last byte of WAL record for last change to this page
<code>pd_checksum</code>	<code>uint16</code>	2 bytes	Page checksum
<code>pd_flags</code>	<code>uint16</code>	2 bytes	Flag bits
<code>pd_lower</code>	<code>LocationIndex</code>	2 bytes	Offset to start of free space
<code>pd_upper</code>	<code>LocationIndex</code>	2 bytes	Offset to end of free space
<code>pd_special</code>	<code>LocationIndex</code>	2 bytes	Offset to start of special space
<code>pd_pagesize_version</code>	<code>uint16</code>	2 bytes	Page size and layout version number information
<code>pd_prune_xid</code>	<code>TransactionId</code>	4 bytes	Oldest unpruned XMAX on page, or zero if none

All the details can be found in `src/include/storage/bufpage.h`.

Following the page header are item identifiers (`ItemIdData`), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space.

The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (`ItemPointer`, also known as `CTID`) created by consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named `HeapTupleHeaderData`, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page's left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 67.4. The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the `MAXALIGN` distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, `t_natts` bits altogether). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a `MAXALIGN` multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

**Table 67.4. HeapTupleHeaderData Layout**

Field	Type	Length	Description
<code>t_xmin</code>	<code>TransactionId</code>	4 bytes	insert XID stamp
<code>t_xmax</code>	<code>TransactionId</code>	4 bytes	delete XID stamp
<code>t_cid</code>	<code>CommandId</code>	4 bytes	insert and/or delete CID stamp (overlays with <code>t_xvac</code> )
<code>t_xvac</code>	<code>TransactionId</code>	4 bytes	XID for VACUUM operation moving a row version
<code>t_ctid</code>	<code>ItemPointerData</code>	6 bytes	current TID of this or newer row version
<code>t_infomask2</code>	<code>uint16</code>	2 bytes	number of attributes, plus various flag bits
<code>t_infomask</code>	<code>uint16</code>	2 bytes	various flag bits
<code>t_hoff</code>	<code>uint8</code>	1 byte	offset to user data

All the details can be found in `src/include/access/htup_details.h`.

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (`attlen = -1`) then it's a bit more complicated. All variable-length data types share the common header structure

`struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 67.2).

---

# Chapter 68. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing by a program named `genbki.pl`, which reads some specially formatted C header files in the `src/include/catalog/` directory of the source tree. The created BKI file is called `postgres.bki` and is normally installed in the `share` subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

## 68.1. BKI File Format

This section describes how the backend interprets BKI files. This description will be easier to understand if the `postgres.bki` file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with `#` are ignored.

## 68.2. BKI Commands

```
create tablename tableoid [bootstrap] [shared_relation] [without_oids] [rowtype_oid oid] (name1
= type1 [FORCE NOT NULL | FORCE NULL ] [, name2 = type2 [FORCE NOT NULL | FORCE NULL ], ...])
```

Create a table named `tablename`, and having the OID `tableoid`, with the columns given in parentheses.

The following column types are supported directly by `bootstrap.c`: `bool`, `bytea`, `char (1 byte)`, `name`, `int2`, `int4`, `regproc`, `regclass`, `regtype`, `text`, `oid`, `tid`, `xid`, `cid`, `int2vector`, `oidvector`, `_int4 (array)`, `_text (array)`, `_oid (array)`, `_char (array)`, `_aclitem (array)`. Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any built-in type.)

When `bootstrap` is specified, the table will only be created on disk; nothing is entered into `pg_class`, `pg_attribute`, etc, for it. Thus the table will not be accessible by ordinary SQL operations until such entries are made the hard way (with `insert` commands). This option is used for creating `pg_class` etc themselves.

The table is created as shared if `shared_relation` is specified. It will have OIDs unless `without_oids` is specified. The table's row type OID (`pg_type` OID) can optionally be specified via the `rowtype_oid` clause; if not specified, an OID is automatically generated for it. (The `rowtype_oid` clause is useless if `bootstrap` is specified, but it can be provided anyway for documentation.)

```
open tablename
```

Open the table named `tablename` for insertion of data. Any currently open table is closed.

```
close [tablename]
```

Close the open table. The name of the table can be given as a cross-check, but this is not required.

```
insert [OID = oid_value] ( value1 value2 ... )
```

Insert a new row into the open table using *value1*, *value2*, etc., for its column values and *oid\_value* for its OID. If *oid\_value* is zero (0) or the clause is omitted, and the table has OIDs, then the next available OID is assigned.

NULL values can be specified using the special key word `_null_`. Values containing spaces must be double quoted.

```
declare [unique] index indexname indexoid on tablename using amname ( opclass1 name1 [, ...] )
```

Create an index named *indexname*, having OID *indexoid*, on the table named *tablename*, using the *amname* access method. The fields to index are called *name1*, *name2* etc., and the operator classes to use are *opclass1*, *opclass2* etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

```
declare toast toasttableoid toastindexoid on tablename
```

Create a TOAST table for the table named *tablename*. The TOAST table is assigned OID *toasttableoid* and its index is assigned OID *toastindexoid*. As with `declare index`, filling of the index is postponed.

```
build indices
```

Fill in the indices that have previously been declared.

## 68.3. Structure of the Bootstrap BKI File

The `open` command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are `pg_class`, `pg_attribute`, `pg_proc`, and `pg_type`.) To allow those tables themselves to be filled, `create` with the `bootstrap` option implicitly opens the created table for data insertion.

Also, the `declare index` and `declare toast` commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the `postgres.bki` file has to be:

1. `create bootstrap` one of the critical tables
2. `insert` data describing at least the critical tables
3. `close`
4. Repeat for the other critical tables.
5. `create` (without `bootstrap`) a noncritical table
6. `open`
7. `insert` desired data
8. `close`
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. `build indices`

There are doubtless other, undocumented ordering dependencies.

## 68.4. Example

The following sequence of commands will create the table `test_table` with OID 420, having two columns `cola` and `colb` of type `int4` and `text`, respectively, and insert two rows into the table:

```
create test_table 420 (cola = int4, colb = text)
open test_table
insert OID=421 ( 1 "value1" )
insert OID=422 ( 2 _null_ )
close test_table
```

---

# Chapter 69. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

## 69.1. Row Estimation Examples

The examples shown below use tables in the regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN
```

```
-----  
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples  
-----+-----  
358 | 10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

```
QUERY PLAN
```

```
-----  
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)  
Recheck Cond: (unique1 < 1000)  
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)  
Index Cond: (unique1 < 1000)
```

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarltsel`. The `scalarltsel` function retrieves the histogram for `unique1` from `pg_statistic`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats  
WHERE tablename='tenk1' AND attname='unique1';
```

```
histogram_bounds
```

```
-----  
{0, 993, 1997, 3050, 4040, 5036, 5957, 7057, 8029, 9016, 9995}
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
            = (1 + (1000 - 993)/(1997 - 993))/10
            = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
      = 10000 * 0.100697
      = 1007 (rounding off)
```

Next let's consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac          | 0
n_distinct         | 676
most_common_vals   |
{EJAAAA, BBAAAA, CRAAAA, FCAAAA, FEAAAA, GSAAAA, JOAAAA, MCAAAA, NAAAAA, WGAAAA}
most_common_freqs | {0.003333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003}
```

Since `CRAAAA` appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```
selectivity = mcf[3]
            = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```
rows = 10000 * 0.003
      = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```
selectivity = (1 - sum(mvf)) / (num_distinct - num_mcv)
            = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 +
                    0.003 + 0.003 + 0.003 + 0.003)) / (676 - 10)
            = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```
rows = 10000 * 0.0014559
      = 15 (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

histogram\_bounds

```
-----
{AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
            = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
            = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
            = 0.01833333 + 0.298387 * 0.96966667
            = 0.307669
```

```
rows = 10000 * 0.307669
      = 3077 (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx'::name)
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 = 'xxx')
              = 0.100697 * 0.0014559
              = 0.0001466
```

```
rows        = 10000 * 0.0001466
              = 1 (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;
```

QUERY PLAN

```
-----
Nested Loop (cost=4.64..456.23 rows=50 width=488)
-> Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)
    Recheck Cond: (unique1 < 50)
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)
    Index Cond: (unique1 < 50)
-> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)
    Index Cond: (unique2 = t1.unique2)
```

The restriction on tenk1, unique1 < 50, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the unique1 histogram:

```
selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max - bucket[1].min))/num_buckets
              = (0 + (50 - 0)/(993 - 0))/10
              = 0.005035
```

```
rows        = 10000 * 0.005035
              = 50 (rounding off)
```

The restriction for the join is t2.unique2 = t1.unique2. The operator is just our familiar =, however the selectivity function is obtained from the oprjoin column of pg\_operator, and is eqjoinsel. eqjoinsel looks up the statistical information for both tenk2 and tenk1:

```
SELECT tablename, null_frac,n_distinct, most_common_vals FROM pg_stats
```

```
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

tablename	null_frac	n_distinct	most_common_vals
tenk1	0	-1	
tenk2	0	-1	

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

```
selectivity = (1 - null_frac1) * (1 - null_frac2) * min(1/num_distinct1, 1/
num_distinct2)
             = (1 - 0) * (1 - 0) / max(10000, 10000)
             = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```
rows = (outer_cardinality * inner_cardinality) * selectivity
      = (50 * 10000) * 0.0001
      = 50
```

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from  $50 * 1$ , that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any `WHERE` clauses) is done in `src/backend/optimizer/util/plancat.c`. The generic logic for clause selectivities is in `src/backend/optimizer/path/clausesel.c`. The operator-specific selectivity functions are mostly found in `src/backend/utils/adt/selfuncs.c`.

## 69.2. Multivariate Statistics Examples

### 69.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```
CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1, 10000) s(i);
ANALYZE t;
```

As explained in Section 14.2, the planner can determine cardinality of `t` using the number of pages and rows obtained from `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';
```

relpages	reltuples
45	10000

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a WHERE condition on the a column:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1;
          QUERY PLAN
-----
Seq Scan on t  (cost=0.00..170.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: (a = 1)
  Rows Removed by Filter: 9900
```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the WHERE condition to use the b column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with AND:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
          QUERY PLAN
-----
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs ANALYZE to calculate functional-dependency multivariate statistics on the two columns:

```
CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
          QUERY PLAN
-----
Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

## 69.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a GROUP BY clause. When GROUP BY lists a single column, the n-distinct estimate (which is visible as the estimated number of rows returned by the HashAggregate node) is very accurate:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a;
          QUERY PLAN
-----
HashAggregate  (cost=195.00..196.00 rows=100 width=12) (actual rows=100 loops=1)
  Group Key: a
  -> Seq Scan on t  (cost=0.00..145.00 rows=10000 width=4) (actual rows=10000
  loops=1)
```

But without multivariate statistics, the estimate for the number of groups in a query with two columns in GROUP BY, as in the following example, is off by an order of magnitude:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
          QUERY PLAN
-----
HashAggregate  (cost=220.00..230.00 rows=1000 width=16) (actual rows=100 loops=1)
```

```

Group Key: a, b
-> Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
loops=1)

```

By redefining the statistics object to include n-distinct counts for the two columns, the estimate is much improved:

```

DROP STATISTICS stts;
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
                                QUERY PLAN

```

```

-----
HashAggregate  (cost=220.00..221.00 rows=100 width=16) (actual rows=100 loops=1)
  Group Key: a, b
  -> Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
loops=1)

```

## 69.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.

# Appendix A. Error Codes

All messages emitted by the server are assigned five-character error codes that follow the SQL standard's conventions for "SQLSTATE" codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A.1 lists all the error codes defined in 10.1.1. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a "standard" error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column "Condition Name" is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a `unique_violation` error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

**Table A.1. Error Codes**

Error Code	Condition Name
<b>Class 00 — Successful Completion</b>	
00000	successful_completion
<b>Class 01 — Warning</b>	
01000	warning
0100C	dynamic_result_sets_returned
01008	implicit_zero_bit_padding
01003	null_value_eliminated_in_set_function
01007	privilege_not_granted
01006	privilege_not_revoked
01004	string_data_right_truncation
01P01	deprecated_feature
<b>Class 02 — No Data (this is also a warning class per the SQL standard)</b>	
02000	no_data
02001	no_additional_dynamic_result_sets_returned
<b>Class 03 — SQL Statement Not Yet Complete</b>	
03000	sql_statement_not_yet_complete
<b>Class 08 — Connection Exception</b>	
08000	connection_exception

## Error Codes

<b>Error Code</b>	<b>Condition Name</b>
08003	connection_does_not_exist
08006	connection_failure
08001	sqlclient_unable_to_establish_sqlconnection
08004	sqlserver_rejected_establishment_of_sqlconnection
08007	transaction_resolution_unknown
08P01	protocol_violation
<b>Class 09 – Triggered Action Exception</b>	
09000	triggered_action_exception
<b>Class 0A – Feature Not Supported</b>	
0A000	feature_not_supported
<b>Class 0B – Invalid Transaction Initiation</b>	
0B000	invalid_transaction_initiation
<b>Class 0F – Locator Exception</b>	
0F000	locator_exception
0F001	invalid_locator_specification
<b>Class 0L – Invalid Grantor</b>	
0L000	invalid_grantor
0LP01	invalid_grant_operation
<b>Class 0P – Invalid Role Specification</b>	
0P000	invalid_role_specification
<b>Class 0Z – Diagnostics Exception</b>	
0Z000	diagnostics_exception
0Z002	stacked_diagnostics_accessed_without_active_handler
<b>Class 20 – Case Not Found</b>	
20000	case_not_found
<b>Class 21 – Cardinality Violation</b>	
21000	cardinality_violation
<b>Class 22 – Data Exception</b>	
22000	data_exception
2202E	array_subscript_error
22021	character_not_in_repertoire
22008	datetime_field_overflow
22012	division_by_zero

# Appendix B. Date/Time Support

uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

## B.1. Date/Time Input Interpretation

The date/time type inputs are all decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
  - a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
  - b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., *America/New\_York*).
  - c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., *19990113* for January 13, 1999) or time (e.g., *141516* for 14:15:16).
  - d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is a text string, match up with possible strings:
  - a. Do a binary-search table lookup for the token as a time zone abbreviation.
  - b. If not found, do a similar binary-search table lookup to match the token as either a special string (e.g., *today*), day (e.g., *Thursday*), month (e.g., *January*), or noise word (e.g., *at*, *on*).
  - c. If still not found, throw an error.
3. When the token is a number or number field:
  - a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., *19990118* or *990118*). The interpretation is *YYYYMMDD* or *YYMMDD*.
  - b. If the token is three digits and a year has already been read, then interpret as day of year.
  - c. If four or six digits and a year has already been read, then interpret as a time (*HHMM* or *HHMMSS*).
  - d. If three or more digits and no date fields have yet been found, interpret as a year (this forces *yy-mm-dd* ordering of the remaining date fields).
  - e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: *mm-dd-yy*, *dd-mm-yy*, or *yy-mm-dd*. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)
5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

### Tip

Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., *0099* is AD 99).

## B.2. Date/Time Key Words

Table B.1 shows the tokens that are recognized as names of months.

**Table B.1. Month Names**

Month	Abbreviations
January	Jan
February	Feb
March	Mar
April	Apr
May	
June	Jun
July	Jul
August	Aug
September	Sep, Sept
October	Oct
November	Nov
December	Dec

Table B.2 shows the tokens that are recognized as names of days of the week.

**Table B.2. Day of the Week Names**

Day	Abbreviations
Sunday	Sun
Monday	Mon
Tuesday	Tue, Tues
Wednesday	Wed, Weds
Thursday	Thu, Thur, Thurs
Friday	Fri
Saturday	Sat

Table B.3 shows the tokens that serve various modifier purposes.

**Table B.3. Date/Time Field Modifiers**

Identifier	Description
AM	Time is before 12:00
AT	Ignored
JULIAN, JD, J	Next field is Julian Date
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time

## B.3. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, provides a means to customize the set of abbreviations accepted by the server. The `timezone_abbreviations` run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored

in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A *zone\_abbreviation* is just the abbreviation being defined. An *offset* is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, `-18000` would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a *time\_zone\_name* can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

### Tip

Using a simple integer *offset* is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc, containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

### Note

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

**Caution**

Time zone abbreviations defined in the configuration file override non-timezone meanings built into . For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

**Caution**

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

## B.4. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. follows the SQL standard's lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as  $365 \frac{1}{4}$  days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as  $365 + 97 / 400$  days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation  $365+97/400$  is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.  
However, every year divisible by 100 is not a leap year.  
However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems have the `cal` program produce the following:

```
$ cal 9 1752
   September 1752
   S  M Tu  W Th  F  S
       1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places

at various times, does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

The *Julian Date* system is another type of calendar, unrelated to the Julian calendar though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger's father, the Italian scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. treats a Julian Date as running from midnight to midnight.

---

# Appendix C. SQL Key Words

Table C.1 lists all tokens that are key words in the SQL standard and in 10.1.1. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in , but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In Table C.1 in the column for we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying Table C.1 that the fact that a key word is not reserved in does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

# Appendix D. SQL Conformance

This section attempts to outline to what extent conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for .

supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, conforms to at least 160. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that supports, followed by a list of the features defined in SQL:2011 which are not yet supported in . Both of these lists are approximate: There

might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

### Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

## D.1. Supported Features

Identifier	Package	Description	Comment
B012		Embedded C

F111-01		READ UNCOMMITTED isolation level	
F111-02		READ COMMITTED isolation level	

Identifier	Package	Description	Comment
F111-03		REPEATABLE READ isolation level	
F131	Core	Grouped operations	
F131-01	Core	WHERE, GROUP BY, and HAVING clauses supported in queries with grouped views	
F131-02	Core	Multiple tables supported in queries with grouped views	
F131-03	Core	Set functions supported in queries with grouped views	
F131-04	Core	Subqueries with GROUP BY and HAVING clauses and grouped views	
F131-05	Core	Single row SELECT with GROUP BY and HAVING clauses and grouped views	
F171		Multiple schemas per user	
F191	Enhanced integrity management	Referential delete actions	
F200		TRUNCATE TABLE statement	
F201	Core	CAST function	
F202		TRUNCATE TABLE: identity column restart option	
F221	Core	Explicit defaults	
F222		INSERT statement: DEFAULT VALUES clause	
F231		Privilege tables	
F231-01		TABLE_PRIVILEGES view	
F231-02		COLUMN_PRIVILEGES view	
F231-03		USAGE_PRIVILEGES view	
F251		Domain support	
F261	Core	CASE expression	
F261-01	Core	Simple CASE	
F261-02	Core	Searched CASE	
F261-03	Core	NULLIF	
F261-04	Core	COALESCE	

Identifier	Package	Description	Comment
F262		Extended CASE expression	
F271		Compound character literals	
F281		LIKE enhancements	
F302		INTERSECT table operator	
F302-01		INTERSECT DISTINCT table operator	
F302-02		INTERSECT ALL table operator	
F304		EXCEPT ALL table operator	
F311-01	Core	CREATE SCHEMA	
F311-02	Core	CREATE TABLE for persistent base tables	
F311-03	Core	CREATE VIEW	
F311-04	Core	CREATE VIEW: WITH CHECK OPTION	
F311-05	Core	GRANT statement	
F321		User authorization	
F361		Subprogram support	
F381		Extended schema manipulation	
F381-01		ALTER TABLE statement: ALTER COLUMN clause	
F381-02		ALTER TABLE statement: ADD CONSTRAINT clause	
F381-03		ALTER TABLE statement: DROP CONSTRAINT clause	
F382		Alter column data type	
F383		Set column not null clause	
F384		Drop identity property clause	
F386		Set identity column generation clause	
F391		Long identifiers	
F392		Unicode escapes in identifiers	
F393		Unicode escapes in literals	
F401		Extended joined table	

Identifier	Package	Description	Comment
F401-01		NATURAL JOIN	
F401-02		FULL OUTER JOIN	
F401-04		CROSS JOIN	
F402		Named column joins for LOBs, arrays, and multi-sets	
F411	Enhanced datetime facilities	Time zone specification	differences regarding literal interpretation
F421		National character	
F431		Read-only scrollable cursors	
F431-01		FETCH with explicit NEXT	
F431-02		FETCH FIRST	
F431-03		FETCH LAST	
F431-04		FETCH PRIOR	
F431-05		FETCH ABSOLUTE	
F431-06		FETCH RELATIVE	
F441		Extended set function support	
F442		Mixed column references in set functions	
F471	Core	Scalar subquery values	
F481	Core	Expanded NULL predicate	
F491	Enhanced integrity management	Constraint management	
F501	Core	Features and conformance views	
F501-01	Core	SQL_FEATURES view	
F501-02	Core	SQL_SIZING view	
F501-03	Core	SQL_LANGUAGES view	
F502		Enhanced documentation tables	
F502-01		SQL_SIZING_PROFILES view	
F502-02		SQL_IMPLEMENTATION_INFO view	
F502-03		SQL_PACKAGES view	
F531		Temporary tables	
F555	Enhanced datetime facilities	Enhanced seconds precision	
F561		Full value expressions	
F571		Truth value tests	

Identifier	Package	Description	Comment
F591		Derived tables	
F611		Indicator data types	
F641		Row and table constructors	
F651		Catalog name qualifiers	
F661		Simple tables	
F672		Retrospective check constraints	
F690		Collation support	but no character set support
F692		Extended collation support	
F701	Enhanced integrity management	Referential update actions	
F711		ALTER domain	
F731		INSERT column privileges	
F751		View CHECK enhancements	
F761		Session management	
F762		CURRENT_CATALOG	
F763		CURRENT_SCHEMA	
F771		Connection management	
F781		Self-referencing operations	
F791		Insensitive cursors	
F801		Full set function	
F850		Top-level <order by clause> in <query expression>	
F851		<order by clause> in subqueries	
F852		Top-level <order by clause> in views	
F855		Nested <order by clause> in <query expression>	
F856		Nested <fetch first clause> in <query expression>	
F857		Top-level <fetch first clause> in <query expression>	
F858		<fetch first clause> in subqueries	

Identifier	Package	Description	Comment
F859		Top-level <fetch first clause> in views	
F860		<fetch first row count> in <fetch first clause>	
F861		Top-level <result offset clause> in <query expression>	
F862		<result offset clause> in subqueries	
F863		Nested <result offset clause> in <query expression>	
F864		Top-level <result offset clause> in views	
F865		<offset row count> in <result offset clause>	
S071	Enhanced object support	SQL paths in function and type name resolution	
S092		Arrays of user-defined types	
S095		Array constructors by query	
S096		Optional array bounds	
S098		ARRAY_AGG	
S111	Enhanced object support	ONLY in query expressions	
S201		SQL-invoked routines on arrays	
S201-01		Array parameters	
S201-02		Array as result type of functions	
S211	Enhanced object support	User-defined cast functions	
S301		Enhanced UNNEST	
T031		BOOLEAN data type	
T071		BIGINT data type	
T121		WITH (excluding RECURSIVE) in query expression	
T122		WITH (excluding RECURSIVE) in subquery	
T131		Recursive query	
T132		Recursive query in subquery	
T141		SIMILAR predicate	
T151		DISTINCT predicate	

Identifier	Package	Description	Comment
T152		DISTINCT predicate with negation	
T171		LIKE clause in table definition	
T172		AS subquery clause in table definition	
T173		Extended LIKE clause in table definition	
T174		Identity columns	
T177		Sequence generator support: simple restart option	
T178		Identity columns: simple restart option	
T191	Enhanced integrity management	Referential action RESTRICT	
T201	Enhanced integrity management	Comparable data types for referential constraints	
T211-01	Active database, Enhanced integrity management	Triggers activated on UPDATE, INSERT, or DELETE of one base table	
T211-02	Active database, Enhanced integrity management	BEFORE triggers	
T211-03	Active database, Enhanced integrity management	AFTER triggers	
T211-04	Active database, Enhanced integrity management	FOR EACH ROW triggers	
T211-05	Active database, Enhanced integrity management	Ability to specify a search condition that must be true before the trigger is invoked	
T211-07	Active database, Enhanced integrity management	TRIGGER privilege	
T212	Enhanced integrity management	Enhanced trigger capability	
T213		INSTEAD OF triggers	
T231		Sensitive cursors	
T241		START TRANSACTION statement	
T271		Savepoints	
T281		SELECT privilege with column granularity	

Identifier	Package	Description	Comment
T285		Enhanced derived column names	
T312		OVERLAY function	
T321-01	Core	User-defined functions with no overloading	
T321-03	Core	Function invocation	
T321-06	Core	ROUTINES view	
T321-07	Core	PARAMETERS view	
T323		Explicit security for external routines	
T325		Qualified SQL parameter references	
T331		Basic roles	
T341		Overloading of SQL-invoked functions and procedures	
T351		Bracketed SQL comments ( <i>/*...*/</i> comments)	
T431	OLAP	Extended grouping capabilities	
T432		Nested and concatenated GROUPING SETS	
T433		Multiargument GROUPING function	
T441		ABS and MOD functions	
T461		Symmetric BETWEEN predicate	
T491		LATERAL derived table	
T501		Enhanced EXISTS predicate	
T551		Optional key words for default syntax	
T581		Regular expression substring function	
T591		UNIQUE constraints of possibly null columns	
T611	OLAP	Elementary OLAP operations	
T613		Sampling	
T614		NTILE function	
T615		LEAD and LAG functions	
T617		FIRST_VALUE and LAST_VALUE function	
T621		Enhanced numeric functions	

Identifier	Package	Description	Comment
T631	Core	IN predicate with one list element	
T651		SQL-schema statements in SQL routines	
T655		Cyclically dependent routines	
X010		XML type	
X011		Arrays of XML type	
X014		Attributes of XML type	
X016		Persistent XML values	
X020		XMLConcat	
X031		XMLElement	
X032		XMLForest	
X034		XMLAgg	
X035		XMLAgg: ORDER BY option	
X036		XMLComment	
X037		XMLPI	
X040		Basic table mapping	
X041		Basic table mapping: nulls absent	
X042		Basic table mapping: null as nil	
X043		Basic table mapping: table as forest	
X044		Basic table mapping: table as element	
X045		Basic table mapping: with target namespace	
X046		Basic table mapping: data mapping	
X047		Basic table mapping: metadata mapping	
X048		Basic table mapping: base64 encoding of binary strings	
X049		Basic table mapping: hex encoding of binary strings	
X050		Advanced table mapping	
X051		Advanced table mapping: nulls absent	
X052		Advanced table mapping: null as nil	
X053		Advanced table mapping: table as forest	

<b>Identifier</b>	<b>Package</b>	<b>Description</b>	<b>Comment</b>
X054		Advanced table mapping: table as element	
X055		Advanced table mapping: with target namespace	
X056		Advanced table mapping: data mapping	
X057		Advanced table mapping: metadata mapping	
X058		Advanced table mapping: base64 encoding of binary strings	
X059		Advanced table mapping: hex encoding of binary strings	
X060		XMLParse: character string input and CONTENT option	
X061		XMLParse: character string input and DOCUMENT option	
X070		XMLSerialize: character string serialization and CONTENT option	
X071		XMLSerialize: character string serialization and DOCUMENT option	
X072		XMLSerialize: character string serialization	
X090		XML document predicate	
X120		XML parameters in SQL routines	
X121		XML parameters in external routines	
X222		XML passing mechanism BY REF	
X301		XMLTable: derived column list option	
X302		XMLTable: ordinality column option	
X303		XMLTable: column default option	
X304		XMLTable: passing a context item	
X400		Name and identifier mapping	

Identifier	Package	Description	Comment
X410		Alter column data type: XML type	

## D.2. Unsupported Features

The following features defined in SQL:2011 are not implemented in this release of . In a few cases, equivalent functionality is available.

Identifier	Package	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B031		Basic dynamic SQL	
B032		Extended dynamic SQL	
B032-01		<describe input statement>	
B033		Untyped SQL-invoked function arguments	
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	
B124		Routine language Fortran	

Identifier	Package	Description	Comment
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B128		Routine language SQL	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support	
E182	Core	Module language	
F054		TIMESTAMP in DATE type precedence list	
F121		Basic diagnostics management	
F121-01		GET DIAGNOSTICS statement	
F121-02		SET TRANSACTION statement: DIAGNOSTICS SIZE clause	
F122		Enhanced diagnostics management	
F123		All diagnostics	
F181	Core	Multiple module support	
F263		Comma-separated predicates in simple CASE expression	
F291		UNIQUE predicate	
F301		CORRESPONDING in query expressions	
F311	Core	Schema definition statement	
F312		MERGE statement	consider INSERT ... ON CONFLICT DO UPDATE
F313		Enhanced MERGE statement	
F314		MERGE statement with DELETE branch	
F341		Usage tables	no ROUTINE_*_USAGE tables
F385		Drop column generation expression clause	
F394		Optional normal form specification	
F403		Partitioned joined tables	
F451		Character set definition	

SQL Conformance

Identifier	Package	Description	Comment
F461		Named character sets	
F492		Optional table constraint enforcement	
F521	Enhanced integrity management	Assertions	
F671	Enhanced integrity management	Subqueries in CHECK	intentionally omitted
F693		SQL-session and client module collations	
F695		Translation support	
F696		Additional translation documentation	
F721		Deferrable constraints	foreign and unique keys only
F741		Referential MATCH types	no partial match yet
F812	Core	Basic flagging	
F813		Extended flagging	
F821		Local table references	
F831		Full cursor update	
F831-01		Updatable scrollable cursors	
F831-02		Updatable ordered cursors	
F841		LIKE_REGEX predicate	
F842		OCCURRENCES_REGEX function	
F843		POSITION_REGEX function	
F844		SUBSTRING_REGEX function	
F845		TRANSLATE_REGEX function	
F846		Octet support in regular expression operators	
F847		Nonconstant regular expressions	
F866		FETCH FIRST clause: PERCENT option	
F867		FETCH FIRST clause: WITH TIES option	
S011	Core	Distinct data types	
S011-01	Core	USER_DEFINED_TYPES view	
S023	Basic object support	Basic structured types	

<b>Identifier</b>	<b>Package</b>	<b>Description</b>	<b>Comment</b>
S024	Enhanced object support	Enhanced structured types	
S025		Final structured types	
S026		Self-referencing structured types	
S027		Create method by specific method name	
S028		Permutable UDT options list	
S041	Basic object support	Basic reference types	
S043	Enhanced object support	Enhanced reference types	
S051	Basic object support	Create table of type	partially supported
S081	Enhanced object support	Subtables	
S091		Basic array support	partially supported
S091-01		Arrays of built-in data types	
S091-02		Arrays of distinct types	
S091-03		Array expressions	
S094		Arrays of reference types	
S097		Array element assignment	
S151	Basic object support	Type predicate	
S161	Enhanced object support	Subtype treatment	
S162		Subtype treatment for references	
S202		SQL-invoked routines on multisets	
S231	Enhanced object support	Structured type locators	
S232		Array locators	
S233		Multiset locators	
S241		Transform functions	
S242		Alter transform statement	
S251		User-defined orderings	
S261		Specific type method	
S271		Basic multiset support	
S272		Multisets of user-defined types	
S274		Multisets of reference types	
S275		Advanced multiset support	
S281		Nested collection types	

Identifier	Package	Description	Comment
S291		Unique constraint on entire row	
S401		Distinct types based on array types	
S402		Distinct types based on distinct types	
S403		ARRAY_MAX_CARDINALITY	
S404		TRIM_ARRAY	
T011		Timestamp in Information Schema	
T021		BINARY and VARBINARY data types	
T022		Advanced support for BINARY and VARBINARY data types	
T023		Compound binary literal	
T024		Spaces in binary literals	
T041	Basic object support	Basic LOB data type support	
T041-01	Basic object support	BLOB data type	
T041-02	Basic object support	CLOB data type	
T041-03	Basic object support	POSITION, LENGTH, LOWER, TRIM, UPPER, and SUBSTRING functions for LOB data types	
T041-04	Basic object support	Concatenation of LOB data types	
T041-05	Basic object support	LOB locator: non-holdable	
T042		Extended LOB data type support	
T043		Multiplier T	
T044		Multiplier P	
T051		Row types	
T052		MAX and MIN for row types	
T053		Explicit aliases for all-fields reference	
T061		UCS support	
T101		Enhanced nullability determination	
T111		Updatable joins, unions, and columns	
T175		Generated columns	

Identifier	Package	Description	Comment
T176		Sequence generator support	
T180		System-versioned tables	
T181		Application-time period tables	
T211	Active database, Enhanced integrity management	Basic trigger capability	
T211-06	Active database, Enhanced integrity management	Support for run-time rules for the interaction of triggers and constraints	
T211-08	Active database, Enhanced integrity management	Multiple triggers for the same event are executed in the order in which they were created in the catalog	intentionally omitted
T251		SET TRANSACTION statement: LOCAL option	
T261		Chained transactions	
T272		Enhanced savepoint management	
T301		Functional dependencies	partially supported
T321	Core	Basic SQL-invoked routines	
T321-02	Core	User-defined stored procedures with no overloading	
T321-04	Core	CALL statement	
T321-05	Core	RETURN statement	
T322	PSM	Declared data type attributes	
T324		Explicit security for SQL routines	
T326		Table functions	
T332		Extended roles	mostly supported
T434		GROUP BY DISTINCT	
T471		Result sets return value	
T472		DESCRIBE CURSOR	
T495		Combined data change and retrieval	different syntax
T502		Period predicates	
T511		Transaction counts	
T521		Named arguments in CALL statement	

Identifier	Package	Description	Comment
T522		Default values for IN parameters of SQL-invoked procedures	supported except DE-FAULT key word in invocation
T561		Holdable locators	
T571		Array-returning external SQL-invoked functions	
T572		Multiset-returning external SQL-invoked functions	
T601		Local cursor references	
T612		Advanced OLAP operations	some forms supported
T616		Null treatment option for LEAD and LAG functions	
T618		NTH_VALUE function	function exists, but some options missing
T619		Nested window functions	
T620		WINDOW clause: GROUPS option	
T641		Multiple column assignment	only some syntax variants supported
T652		SQL-dynamic statements in SQL routines	
T653		SQL-schema statements in external routines	
T654		SQL-dynamic statements in external routines	
M001		Datalinks	
M002		Datalinks via SQL/CLI	
M003		Datalinks via Embedded SQL	
M004		Foreign data support	partially supported
M005		Foreign schema support	
M006		GetSQLString routine	
M007		TransmitRequest	
M009		GetOpts and GetStatistics routines	
M010		Foreign data wrapper support	different API
M011		Datalinks via Ada	
M012		Datalinks via C	
M013		Datalinks via COBOL	
M014		Datalinks via Fortran	
M015		Datalinks via M	
M016		Datalinks via Pascal	

<b>Identifier</b>	<b>Package</b>	<b>Description</b>	<b>Comment</b>
M017		Datalinks via PL/I	
M018		Foreign data wrapper interface routines in Ada	
M019		Foreign data wrapper interface routines in C	different API
M020		Foreign data wrapper interface routines in COBOL	
M021		Foreign data wrapper interface routines in Fortran	
M022		Foreign data wrapper interface routines in MUMPS	
M023		Foreign data wrapper interface routines in Pascal	
M024		Foreign data wrapper interface routines in PL/I	
M030		SQL-server foreign data support	
M031		Foreign data wrapper general routines

X272		XMLValidate: AC-CORDING TO clause	
X273		XMLValidate: ELEMENT clause	
X274		XMLValidate: schema location	
X281		XMLValidate with DOCUMENT option	
X282		XMLValidate with CONTENT option	
X283		XMLValidate with SEQUENCE option	
X284		XMLValidate: NAMESPACE without ELEMENT clause	
X286		XMLValidate: NO NAMESPACE with ELEMENT clause	
X300		XMLTable	XPath only
X305		XMLTable: initializing an XQuery variable	

---

# Appendix E. Release Notes

The release notes contain the significant changes in each release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The *pgsql-committers email list* records all source code changes as well. There is also a *web interface* that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

## E.1. Postgres Pro 10.1.1

**Release Date:** 2017-11-22

### E.1.1. Overview

This release is based on PostgreSQL 10.1 and includes all the new features introduced in PostgreSQL 10, as well as bug fixes implemented in PostgreSQL 10.1. For their detailed description, see PostgreSQL 10 Release Notes and PostgreSQL 10.1 Release Notes, respectively. Other major changes and enhancements are as follows:

- Unified the structure of binary installation packages across all Linux-based distributions. For a minimum server deployment, at least the following packages are now required: `postgrespro-std-10-server`, `postgrespro-std-10`, and `postgrespro-std-10-libs`. On the client side, it is usually enough to install the `postgrespro-std-10` and `postgrespro-std-10-libs` packages. Note that `postgrespro-common` and `postgrespro-client-common` packages are no longer available on Debian-based systems. For details, see Section 16.1.
- You can specify `icu` or `libc` as the default collation provider when initializing a database cluster or creating a database. By default, the `icu` provider is used for all locales except `C` and `POSIX`. For details, see Section 24.2.2.
- In B-tree index, duplicate keys are now stored only once, with item pointers located in posting lists. It can significantly reduce the index size for workloads where the same key appears multiple times.

Core patches from Postgres Pro 9.6 have been applied:

- Covering indices patches (For details, see the `INCLUDE` clause description in `CREATE INDEX`.)
- Fixes to win32 build system
- Added `pgpro_version` SQL function and appropriate defines into `pg_config.h`
- Integrated `PTRACK` patch
- For Windows version of `psql`, enabled support for command-line editing using `libeditline`

The following modules and utilities have been ported from Postgres Pro 9.6:

- `hunspell-dict` (See Hunspell Dictionaries Modules)
- `jquery` (See Section F.26)
- `pg_variables` (See Section F.44)
- `pg_pathman` (See Section F.36)
- `pg_query_state` (See Section F.38)
- `shared-ispell` (See `shared_ispell`)
- `sr_plan` (See `sr_plan`)
- `dump_stat` (See `dump-stat`)
- `pg_buffercache` (See `pg_buffercache`)
- `mchar` (See Section F.29)
- `plantuner` (See Section F.46)
- `fasttrun` (See Section F.17)

- `fulleq` (See Section F.19)
- `online-analyze` (See Section F.30)
- `pg_pathman` (See Section F.36)
- `pg_probackup` utility (See `pg_probackup`)

## E.1.2. Migration to Version 10.1.1

To upgrade to Postgres Pro 10, you can perform a dump/restore using `pg_dumpall`, or use the `pg_upgrade` utility. The first option is safer, while the second is faster and can significantly speed up the upgrade process for large databases.

Starting from Postgres Pro 10, you can specify the default collation provider when initializing the database cluster or creating the database, as explained in Section 24.2.2. You must take it into account when upgrading to this release to avoid breaking indexes and constraints.

### Important

If your current Postgres Pro installation uses ICU, do not update ICU library to a newer version. Otherwise, you cannot upgrade to Postgres Pro 10.

### Important

For PostgreSQL 9.5 and 9.5.1, as well as Postgres Pro 9.5.0.1 and 9.5.1.2, you cannot perform an upgrade to Postgres Pro 10 directly. If you are using one of these versions, upgrade your installation to an intermediate version first, such as Postgres Pro 9.5.2.1.

When using `pg_upgrade`, make sure that `initdb` sets the correct default collation provider for the new database cluster:

- When upgrading from vanilla PostgreSQL, specify `libc` as the default collation provider.
- When upgrading from Postgres Pro, omit the default collation provider option to select the required collation provider automatically. In this case, `libc` provider will be used for databases with C and POSIX locales, as well as for all databases with single-byte encodings, while `icu` provider will be used for all the other cases.

If `pg_upgrade` creates any SQL files in its current directory, run these files to complete the upgrade.

When you are using `pg_dumpall` to perform the upgrade, Postgres Pro uses the collation provider specified with the `initdb` command for the new cluster. In this case, indexes are rebuilt automatically. To avoid issues with collation-dependent constraints, you are recommended to use `libc` provider when upgrading from vanilla PostgreSQL, and omit the provider when upgrading from a previous version of Postgres Pro.

### Note

If the previous Postgres Pro installation contained any indexes or constraints depending on collations other than the default collation of the database, `C`, or `POSIX` in databases with multibyte encodings, such databases could contain some data that violated the specified constraints and made indexes inconsistent. On Windows, this situation can also happen if the database with a multibyte encoding contained any indexes or constraints depending on the default collation with a verbose name, such as `"Russian_Russia[.encoding]"` or `"English_United States[.encoding]"`. In such cases, you can only use `pg_upgrade` to upgrade to Postgres Pro 10, as a dump/restore scenario may be impossible. To resolve these issues, `pg_upgrade` declares such indexes and constraints invalid and creates `reindex_text_indexes.sql` and `validate_text_constraints.sql`, respectively.

When building Postgres Pro manually, you must include ICU using the `--with-icu` option. Otherwise, you cannot upgrade to Postgres Pro 10 from a previous Postgres Pro version.

### Important

For binary installations on Linux systems, the default directories have changed, as compared to Postgres Pro 9.6. Postgres Pro is now installed to the `/opt/pgpro/std-10` directory, while the default database is created in the `/var/lib/pgpro/std-10/data` directory. Server autostart is disabled by default. Make sure to take this into account when upgrading to Postgres Pro 10. For details, see Section 16.1.

## E.2. Postgres Pro 9.6.6.1

**Release date:** 2017-11-14

### E.2.1. Overview

This release is based on PostgreSQL 9.6.6 and Postgres Pro 9.6.5.1. All improvements inherited from PostgreSQL 9.6.6 are listed in PostgreSQL 9.6.6 Release Notes.

Major enhancements over Postgres Pro 9.6.5.1 include:

- Updated `pg_pathman` module to version 1.4.8. (See Section F.36 and Section F.36.1.1.) As compared to version 1.4.3, the following enhancements were introduced:
  - Improved cache invalidation mechanisms.
  - Disabled `COPY partitioned_table TO` command. Use `COPY (SELECT * FROM partitioned_table) TO` instead.
  - Fixed `INSTEAD OF` triggers on views selected from partitioned tables.
  - `ALTER TABLE partitioned_table RENAME TO` now also renames auto naming sequences.
  - Disabled some dangerous optimizations for `SELECT ... FOR SHARE/UPDATE` on PostgreSQL 9.5.
  - Improved error handling in concurrent partitioning background worker.
  - Prohibited execution of queries `DELETE FROM partitioned_table_1 USING partitioned_table_2...` and `UPDATE partitioned_table_1 FROM partitioned_table_2...` if such queries touch more than one partition of `partitioned_table_1`.
  - Fixed a bug causing crashes on `RESET ALL`.
  - Fixed `WHERE` conditions that point to gaps between partitions.
  - Restored compatibility with `pg_repack`.
  - For the full list of changes, see *pg\_pathman Wiki*.
- Updated the `pg_probackup` utility from version 2.0.2 to 2.0.11, which includes the following new features:
  - Password prompt interruption is now handled correctly.
  - The provided passwords are checked to be non-empty.
  - The files that have not changed since the previous backup are not included into the next incremental backup.
  - Database version is now added into backup meta information.
  - Other miscellaneous bugfixes.

### E.2.2. Migration to Version 9.6.6.1

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro version based on any previous PostgreSQL major release, you can perform a dump/restore using `pg_dumpall`, or use the `pg_upgrade` utility. The first option is safer, while the second is faster and can significantly speed up the upgrade process for large databases.

To upgrade from a Postgres Pro version based on the same PostgreSQL major release, a dump/restore is not required. If you are upgrading from Postgres Pro 9.6.5.1, it is enough to install the new version into your current installation directory. When upgrading from Postgres Pro 9.6.4.1 or lower, you must also use the `pgpro_upgrade` script provided in this distribution. This script updates metadata information to handle catalog number format change introduced after Postgres Pro 9.6.4.1. If you are upgrading your Postgres Pro installation from a binary package, the `pgpro_upgrade` script is run automatically, unless you are prompted to run it manually.

### Important

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres). Running `pgpro_upgrade` as root will result in an error.

If you have compiled Postgres Pro from source code or created your database in a non-default location, you must run the `pgpro_upgrade` script manually.

### Note

On RPM-based Linux distributions, if you are upgrading from version 9.6.2.1 or lower, make sure to move the data directory from `pgsql` to the `pgpro` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x, perform a dump/restore using `pg_dumpall`.

## E.3. Postgres Pro 9.6.5.1

**Release date:** 2017-08-31

### E.3.1. Overview

This release is based on Postgres Pro 9.6.4.1 and PostgreSQL 9.6.5.

Major enhancements over Postgres Pro 9.6.4.1 include:

- Updated `pg_pathman` module to version 1.4.3. (See Section F.36 and Section F.36.1.1.) As compared to version 1.4.2, the following enhancements were introduced:
  - Disabled dangerous optimizations for `UPDATE` and `DELETE` on PostgreSQL 9.5.
  - Fixed the following type of query: `DELETE FROM single_table USING partitioned_table`.
  - Fixed the output of the `EXPLAIN INSERT INTO partitioned_table` command when verbose mode is activated.

For a full list of changes, see *pg\_pathman Wiki*.

- Enhanced the `pg_controldata` utility to enable automatic Postgres Pro upgrades using the `pgpro_upgrade` script.

### E.3.2. Migration to Version 9.6.5.1

Depending on your current installation, the upgrade procedure will differ.

To upgrade from a Postgres Pro version based on any previous PostgreSQL major release, you can perform a dump/restore using `pg_dumpall`, or use the `pg_upgrade` utility. The first option is safer, while the second is faster and can significantly speed up the upgrade process for large databases.

To upgrade from a Postgres Pro version based on the same PostgreSQL major release, a dump/restore is not required. Instead of the `pg_upgrade`, you must use the `pgpro_upgrade` script provided in this distri-

bution. This script updates metadata information to handle catalog number format change introduced after Postgres Pro 9.6.4.1. If you are upgrading your Postgres Pro installation from a binary package, the `pgpro_upgrade` script is run automatically, or you are prompted to run it manually.

### **Important**

If you run `pgpro_upgrade` manually, you must stop postgres service. The script must be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides. Running `pgpro_upgrade` as root will result in an error.

If you have compiled Postgres Pro from source code or created your database in a non-default location, you must run the `pgpro_upgrade` script manually.

### **Note**

On RPM-based Linux distributions, if you are upgrading from version 9.6.2.1 or lower, make sure to move the data directory from `pgsql` to the `pgpro` directory before running the `pgpro_upgrade` script.

To migrate from vanilla PostgreSQL 9.6.x, perform a dump/restore using `pg_dumpall`.

## **E.4. Postgres Pro 9.6.4.1**

**Release date:** 2017-08-14

### **E.4.1. Overview**

This release is based on Postgres Pro 9.6.3.3 and PostgreSQL 9.6.4.

Major enhancements over Postgres Pro 9.6.3.3 include:

- Fixed an incorrect catalog check in `pg_dump` that has been added with the previous release.
- Added distribution for Ubuntu 17.10.

### **E.4.2. Migration to Version 9.6.4.1**

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous major release.

A dump/restore is required for those running 9.6.3.3, because catalog number format has been changed for better Postgres Pro identification.

If you are upgrading from vanilla PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## **E.5. Postgres Pro 9.6.3.3**

**Release date:** 2017-07-27

## E.5.1. Overview

This release is based on Postgres Pro 9.6.3.2 and PostgreSQL 9.6.3.

Major enhancements over Postgres Pro 9.6.3.2 include:

- Fix potential data corruption in the `online_analyze` contrib module
- Module `pg_pathman` updated to version 1.4.2

## E.6. Postgres Pro 9.6.3.2

**Release date:** 2017-07-12

### E.6.1. Overview

This release is based on Postgres Pro 9.6.3.1 and PostgreSQL 9.6.3.

Major enhancements over Postgres Pro 9.6.3.1 include:

- Updated the `pg_probackup` backup manager to version 2.0 that includes the following new features:
  - Saving backups for different databases in a single backup catalog
    - Storing backup data in a compressed state to save disk space
    - Extended logging settings
- Added distribution for Debian 9.
- Added upstream patches that fix potential data corruption during freeze.

### E.6.2. Migration to Version 9.6.3.2

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous major release.

A dump/restore is not required for those running 9.6.3.1.

However, if you are upgrading from vanilla PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and `PGDATA` environment variable should be set to the directory where database resides.

## E.7. Postgres Pro 9.6.3.1

**Release date:** 2017-05-15

### E.7.1. Overview

This release is based on Postgres Pro 9.6.2.1 and PostgreSQL 9.6.3.

Major enhancements over Postgres Pro 9.6.2.1 include:

- Added `pg_tsparser` extension for text search.

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word if this word includes:

- underscores
- numbers and letters separated by the hyphen character
- Updated the `pg_pathman` module to version 1.3.2. This version provides compatibility fixes for this release.
- The `sr_plan` module is now working with non-default `search_path` variable.
- Fixed WAL inconsistency bug in covering indexes.
- Added distribution for SUSE Linux Enterprise Server 12 SP1 and Ubuntu 17.04.
- Applied patches to optimize inheritance.
- Updated PTRACK patch to version 1.2.
- Provided performance improvements for queries typical for 1C solutions.

## E.7.2. Migration to Version 9.6.3.1

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous major release.

A dump/restore is not required for those running 9.6.2.1.

However, if you are upgrading from vanilla PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.8. Postgres Pro 9.6.2.1

**Release date:** 2017-02-22

### E.8.1. Overview

This release is based on Postgres Pro 9.6.1.2 and PostgreSQL 9.6.2.

Major enhancements over Postgres Pro 9.6.1.2 include:

- Module `pg_pathman` has been updated to version 1.3 (see Section F.36.1.1).
- The `sr_plan` module is now initialized independently for each database instance.
- Syntax for covering indexes has been changed. Now the keyword `INCLUDING` is replaced by `INCLUDE`. The previous syntax still works, but is deprecated (see Section 11.6).
- RHEL-based distributions are installed in a separate location, so the Postgres Pro database can be installed in parallel with an existing PostgreSQL database.
- Improved the algorithm of automatic TCP-port selection for the case of parallel installation of different versions of the product on Windows systems.
- Updated the `pg_probackup` backup manager:
  - Added `retention show` and `retention purge` commands to implement retention policy.

- Added support for incremental backup of compressed page files. Compressed files are the feature of the Postgres Pro Enterprise.
- Fixed `validate` command. The `backup_id` parameter is optional now.

## E.8.2. Migration to Version 9.6.2.1

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous major release.

A dump/restore is not required for those running 9.6.1.2.

However, if you are upgrading from vanilla PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.9. Postgres Pro 9.6.1.2

**Release date:** 2016-12-14

### E.9.1. Overview

This release is based on Postgres Pro 9.6.1.1 and upstream PostgreSQL patches.

Major enhancements over Postgres Pro 9.6.1.1 include:

Several modules to support 1C Enterprise added:

- `mchar` (See Section F.29)
- `fulleq` (See Section F.19)
- `fasttrun` (See Section F.17)
- `online_analyze` (See Section F.30)
- `plantuner` (See Section F.46)

Also, following core changes were added to support 1C:

- Application level locks
- Optimization of range conditions in the WHERE clause

Modules has been updated

- `pg_pathman` to version 1.2.2 (See Section F.36)

Backup manager `pg_arman` has been replaced to `pg_probackup` (Version 1.0).

### E.9.2. Migration to Version 9.6.1.2

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous major release.

A dump/restore is not required for those running 9.6.1.1.

However, if you are upgrading from vanilla PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running script, you should stop `postgres` service. Script should be run as user, owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides.

## E.10. Postgres Pro 9.6.1.1

**Release date:** 2016-11-01

### E.10.1. Overview

This release is based on PostgreSQL 9.6.1.

Major enhancements over Postgres Pro 9.6.0.1 include:

Added fix for `pg_buffercache` module, which improves database response in the case of connected monitoring tools.

Added new `pgpro_edition()` function, which returns a name of Postgres Pro edition, i.e. `standard` or `enterprise`.

### E.10.2. Migration to Version 9.6.1.1

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous major release.

A dump/restore is not required for those running 9.6.0.1.

However, if you are upgrading from vanilla PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running script, you should stop `postgres` service. Script should be run as user, owning the database (typically `postgres`) and `PGDATA` environment variable should be set to the directory where database resides.

## E.11. Postgres Pro 9.6.0.1

**Release date:** 2016-10-12

### E.11.1. Overview

This release is based on PostgreSQL 9.6.0.

Major enhancements over PostgreSQL 9.6.0 include:

Core patches from Postgres Pro 9.5 has been applied:

- Covering indices patch by Anastasia Lubennikova (Commit: 91b4e25614247833d7960c49d783f69b90c0c149) (Details: <http://www.postgresql.org/message-id/f90aa60a-b67f-95b5-d9f5-f5d8ced178c6@postgrespro.ru/>)

ICU patch (Commit: ee711324f31cc039e656ea45c54abd0cf8ea3e41)

Fixes to win32 build system (Commit: 84fa653ee00ebe54f591b18e3664fa6d5889224f)

Added `pgpro_version` SQL function and appropriate defines into `pg_config.h` (Commit: 671a7525541aa3eece366dae4249aa43a56a2168)

Integrated PTRACK patch (Commit: cea0987364070600fe640df0050d285b53cafb00)

Added order by to `index_including` test to make 32-bit FreeBSD happy (Commit: fd9fc27d40b5d-d4db611418bb848760154ec9f55)

Modules has been ported from Postgres Pro 9.5

- `hunspell-dict` (See Hunspell Dictionaries Modules)
- `jsquery` (See Section F.26)
- `pg_variables` (See Section F.44)
- `pg_pathman` (See Section F.36)
- `pg_query_state` (See Section F.38)
- `shared-ispell` (See `shared_ispell`)
- `sr_plan` (See `sr_plan`)
- `dump_stat` (See `dump-stat`)

Tools has been ported from Postgres Pro 9.5

- `pg_arman`

## E.11.2. Migration to Version 9.6.0.1

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Dump/restore is not necessary when migrating from PostgreSQL 9.6.x to Postgres Pro 9.6.x.y.

When upgrading from previous releases of Postgres Pro or from vanilla PostgreSQL 9.6.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running script, you should stop postgres service. Script should be run as user, owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.12. Postgres Pro 9.5.10.1

**Release date:** 2017-11-14

### E.12.1. Overview

This release is based on PostgreSQL 9.5.10 and Postgres Pro 9.5.9.1. All improvements inherited from PostgreSQL 9.5.10 are listed in PostgreSQL 9.5.10 Release Notes.

Major enhancements over Postgres Pro 9.5.9.1 include:

- Updated `pg_pathman` module to version 1.4.8. (See Section F.36 and Section F.36.1.1.) As compared to version 1.4.3, the following enhancements were introduced:
  - Improved cache invalidation mechanisms.

- Disabled `COPY partitioned_table TO` command. Use `COPY (SELECT * FROM partitioned_table) TO` instead.
- Fixed `INSTEAD OF` triggers on views selected from partitioned tables.
- `ALTER TABLE partitioned_table RENAME TO` now also renames auto naming sequences.
- Disabled some dangerous optimizations for `SELECT ... FOR SHARE/UPDATE` on PostgreSQL 9.5.
- Improved error handling in concurrent partitioning background worker.
- Prohibited execution of queries `DELETE FROM partitioned_table_1 USING partitioned_table_2...` and `UPDATE partitioned_table_1 FROM partitioned_table_2...` if such queries touch more than one partition of `partitioned_table_1`.
- Fixed a bug causing crashes on `RESET ALL`.
- Fixed `WHERE` conditions that point to gaps between partitions.
- Restored compatibility with `pg_repack`.
- For the full list of changes, see *pg\_pathman Wiki*.

## E.12.2. Migration to Version 9.5.10.1

Depending on your current installation, the upgrade procedure will differ.

If you are running Postgres Pro 9.5.9.1, it is enough to install the 9.5.10.1 version into the same directory. For earlier Postgres Pro versions, `pgpro_upgrade` script is required to complete the upgrade:

- If you are upgrading your installation from a binary package, and your database is in the default location, `pgpro_upgrade` is run automatically, unless you are prompted to run it manually.
- If you compiled Postgres Pro from source code or created your database in a non-default location, you must run `pgpro_upgrade` script manually.

### Important

Before launching `pgpro_upgrade` manually, you must stop the `postgres` service. The script must be run on behalf of the user owning the database (typically `postgres`). Running `pgpro_upgrade` as root will result in an error.

To migrate to this version from vanilla PostgreSQL, perform a dump/restore using `pg_dumpall`.

## E.13. Postgres Pro 9.5.9.1

**Release date:** 2017-09-01

### E.13.1. Overview

This release is based on PostgreSQL 9.5.9 and Postgres Pro 9.5.8.1.

Major enhancements over Postgres Pro 9.5.8.1 include:

- Updated `pg_pathman` module to version 1.4.3. (See Section F.36 and Section F.36.1.1.) As compared to version 1.4.2, the following enhancements were introduced:
  - Disabled dangerous optimizations for `UPDATE` and `DELETE` on PostgreSQL 9.5.
  - Fixed the following type of query: `DELETE FROM single_table USING partitioned_table`.
  - Fixed the output of the `EXPLAIN INSERT INTO partitioned_table` command when verbose mode is activated.
  - For a full list of changes, see *pg\_pathman Wiki*.

### E.13.2. Migration to Version 9.5.9.1

A dump/restore is not required for those running 9.5.8.1.

However, if you are upgrading from a version earlier than 9.5.x.x or vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.14. Postgres Pro 9.5.8.1

**Release date:** 2017-08-14

### E.14.1. Overview

This release is based on PostgreSQL 9.5.8 and Postgres Pro 9.5.7.1.

Major enhancements over Postgres Pro 9.5.7.1 include:

- Updated `pg_pathman` module to version 1.4.2. (See Section F.36 and Section F.36.1.1.) As compared to version 1.4, the following enhancements were introduced:
  - Added support for partitioning by expression, for both range and hash partitioning.
  - Enabled manual creation of range partitions by composite key.
  - Enabled range partitioning by text key.
  - Multiple bug fixes and improvements. For a full list of changes, see *pg\_pathman Wiki*.
- Added distribution for Ubuntu 17.10.
- Fixed `ALTER COLUMN` operation for tables with indexes.

### E.14.2. Migration to Version 9.5.8.1

A dump/restore is not required for those running 9.5.7.1.

However, if you are upgrading from a version earlier than 9.5.x.x or vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.15. Postgres Pro 9.5.7.2

**Release date:** 2017-07-12

### E.15.1. Overview

This release is based on PostgreSQL 9.5.7 and Postgres Pro 9.5.7.1.

Major enhancements over Postgres Pro 9.5.7.1 include:

- Added upstream patches that fix potential data corruption during freeze.
- Added distribution for Debian 9.

### E.15.2. Migration to Version 9.5.7.2

A dump/restore is not required for those running 9.5.7.1.

However, if you are upgrading from a version earlier than 9.5.x.x or vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.16. Postgres Pro 9.5.7.1

**Release date:** 2017-05-15

### E.16.1. Overview

This release is based on PostgreSQL 9.5.7 and Postgres Pro 9.5.6.1.

Major enhancements over Postgres Pro 9.5.6.1 include:

- Added distribution for SUSE Linux Enterprise Server 12 SP1 and Ubuntu 17.04.

### E.16.2. Migration to Version 9.5.7.1

A dump/restore is not required for those running 9.5.6.1.

However, if you are upgrading from a version earlier than 9.5.x.x or vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.17. Postgres Pro 9.5.6.1

**Release date:** 2016-02-22

### E.17.1. Overview

This release is based on PostgreSQL 9.5.6 and Postgres Pro 9.5.5.1.

Major enhancements over Postgres Pro 9.5.5.1 include:

- Module `pg_pathman` has been updated to version 1.3 (See Section F.36 and Section F.36.1.1).
- The `sr_plan` module is now initialized independently for each database instance.
- Applied fixes for covering indexes.
- RHEL-based distributions are installed in a separate location, so the product can be installed in parallel with an existing PostgreSQL.

### E.17.2. Migration to Version 9.5.6.1

A dump/restore is not required for those running 9.5.5.1.

However, if you are upgrading from a version earlier than 9.5.x.x or vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in a non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running the script, you should stop postgres service. Script should be run on behalf of the user owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.18. Postgres Pro 9.5.5.1

**Release date:** 2016-11-01

### E.18.1. Overview

This release is based on PostgreSQL 9.5.5

Major enhancements over Postgres Pro 9.5.4.1 include:

- Module `pg_pathman` has been updated to version 1.1.1 (See Section F.36)

Added `pg_query_state` module (See Section F.38)

Updates for `pg_arman` backup utility

Fixes for covering indexes, correct work with more than 3-level indexes.

### E.18.2. Migration to Version 9.5.5.1

A dump/restore is not required for those running 9.5.4.1.

However, if you are upgrading from a version earlier than 9.5.4.1 or vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running script, you should stop postgres service. Script should be run as user, owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.19. Postgres Pro 9.5.4.1

**Release date:** 2016-08-16

### E.19.1. Overview

This release is based on PostgreSQL 9.5.4

Major enhancements over Postgres Pro 9.5.3.2 include:

- The distance semantic of the FTS phrase operator has been changed: less-or-equal replaced by exact match (For details see: Section 12.1.2).
- The precedence of the phrase operator has been changed. The operator `<->` has now higher precedence than `&` (AND) operator.

On Microsoft Windows systems:

- The WinEditLine library is integrated to implement autocomplete in psql console. The psql default encoding is changed to UTF-8.

## E.19.2. Migration to Version 9.5.4.1

A dump/restore is not required for those running 9.5.3.2.

However, if you are upgrading from a version earlier than 9.5.3.2 or vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running script, you should stop postgres service. Script should be run as user, owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.19.3. Potential problems

Plperl extension loading may not work on Microsoft Windows.

## E.20. Postgres Pro 9.5.3.2

**Release date:** 2016-06-27

### E.20.1. Overview

This release is based on PostgreSQL 9.5.3

Major enhancement over the Postgres Pro 9.5.3.1 include:

- New version of `pg_arman` (Unix only) with enhanced incremental backup capabilities
- Various fixes and improvements in the `pg_pathman`
- Fixed problem with dumping of vanilla PostgreSQL database with Postgres Pro `pg_dump` utility

## E.21. Postgres Pro 9.5.3.1

**Release date:** 2016-05-12

### E.21.1. Overview

This release is based on PostgreSQL 9.5.3

Major enhancement in the Postgres Pro 9.5.3.1 over Postgres Pro 9.5.2.1 include:

- Russian translation of documentation is included
- Postgres Pro own system of catalog upgrade is included.
- Covering indexes ported from 9.6 and upgrade scripts are added. Fixed `pg_dump` of covering indexes.
- Phrase search is now compatible with upcoming 9.6 release
- Added `pg_variables` contrib module, which provides session-wide variables, similar with Oracle package variables
- Lockfree Pin/UnpinBuffer backported from 9.6

### E.21.2. Upgrading from previous releases

When upgrading from previous releases of Postgres Pro or from vanilla PostgreSQL 9.5.x, some catalog changes should be applied.

If you use binary packages, and your database is in the default location, this upgrade should be performed automatically. If you've compiled Postgres Pro from source or create your database in non-default location, running `initdb` manually, you should run `pgpro_upgrade` script provided in this distribution.

Before running script, you should stop postgres service. Script should be run as user, owning the database (typically postgres) and PGDATA environment variable should be set to the directory where database resides.

## E.22. Postgres Pro 9.5.2.1

**Release date:** 2016-04-01

### E.22.1. Overview

This release is based on PostgreSQL 9.5.2.

Note that Postgres Pro doesn't suffer from abbreviated keys problem, mentioned in the changes of upstream 9.5.2 release. When build with `--with-icu` option, Postgres Pro doesn't use string comparison functions from system C library, and uses portable implementations from `libicu`.

Major enhancement in the Postgres Pro 9.5.2.1 over Postgres Pro 9.5.1.2 include:

- Include `pg_pathman` module which provides functions for declarative partitioning and optimizes query execution plans for partitioned tables.
- Include `pg_arman` incremental backup utility. It is considered an experimental feature, so it is build as separate package on Linux and is not available for Windows yet. Documentation is also provided separately
- `version()` SQL function now returns PostgreSQL 9.5.2, as in vanilla PostgreSQL, because some client frameworks such as SQL Alchemy are confused seeing Postgres Pro here. Function `pgpro_version` is provided to report Postgres Pro release.

## E.23. Postgres Pro 9.5.1.2

**Release date:** 2016-03-02

### E.23.1. Overview

Major enhancements in Postgres Pro 9.5.1.2 over Postgres Pro 9.5.1.1 include:

- Include `jsquery` module (query language for jsonb fields).
- Improvement of substring similarity search (`pg_trgm` module).
- Support of loading of the `ispell` dictionaries into shared memory.

### E.23.2. Changes

Below you will find a detailed account of the changes between Postgres Pro 9.5.1.2 and the previous minor release.

#### E.23.2.1. Additional Modules

- `jsquery` module - query operators for jsonb structures. Support GIN indexes. Authors Teodor Sigaev, Alexander Korotkov, Oleg Bartunov.
- Improvements of `pg_trgm` module. Substring similarity search improved (Artur Zakirov)
- `shared_ispell` module Support for loading fulltext-search dictionaries into shared memory. Improves speed, because there is now no need to load `hspell` dictionary into each session again and again. (Artur Zakirov)

## E.24. Postgres Pro 9.5.0.1

**Release date:** 2016-02-01

### E.24.1. Overview

Major enhancements in Postgres Pro 9.5 over PostgreSQL 9.5 include:

- Scalability improvements for multicore/multeprocessor systems.
- Covering indexes.
- Use portable implementation of the internationalization functions (libcicu) instead of system specific.
- Speedup of two-phase commit.
- Contrib module `pg_trgm` supports substring searches.
- Save-restore execution plan extension.
- Dump/restore database statistics.
- Some hunspell dictionaries for full-text search are bundled with distribution.
- Phrase search support in full text search.

The above items are explained in more detail in the sections below.

### E.24.2. Migration to Postgres Pro 9.5

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Dump/restore is not necessary when migrating from PostgreSQL 9.5 to Postgres Pro 9.5.

### E.24.3. Changes

Below you will find a detailed account of the changes between Postgres Pro 9.5 and PostgreSQL 9.5.

#### E.24.3.1. Server

##### E.24.3.1.1. Indexes

- Covering indexes. Now `CREATE INDEX` supports optional `INCLUDING` clause, which allows to include additional columns, which would not affect sort order or uniqueness, but allow speed up some queries using index only scans.

##### E.24.3.1.2. General Performance

- Scalability improvements for multicore/multiprocessor systems:
  - Resource owner optimisation for complicated queries: now resource lists has constant access time, which improves performance for heavily partitioned tables and queries which use hundreds of tables.
  - Fix lock contention for `HASHHDR.mutex`. (Alexander Alexeev). This prevents Postgres from waiting for lock up to several milliseconds when modifying state, shared between processes.
  - Improve buffer manager concurrency for multicore architectures.
  - Improve `LWLock` concurrency for Power8 architecture.
- Speedup two phase commit by skipping two phase state files in normal path 2PC state info is written only to WAL at `PREPARE`, then read back from WAL at `COMMIT PREPARED/ABORT PREPARED`. Prepared transactions that live past one `bufmgr` checkpoint cycle will be written to disk in

the same form as previously. Crash recovery path is not altered. Measured performance gains of 50-100% for short 2PC transactions by completely avoiding writing files and fsyncing. Other optimizations still available, further patches in related areas expected.

Stas Kelvich and heavily edited by Simon Riggs.

Based upon earlier ideas and patches by Michael Paquier and Heikki Linnakangas, a concrete example of how Postgres-XC has fed back ideas into PostgreSQL.

Reviewed by Michael Paquier, Jeff Janes and Andres Freund Performance testing by Jesper Pederesen.

#### **E.24.3.1.3. Full text search**

- Phrase search - it is now possible to specify order of words in the text search query.
- Improved hunspell dictionaries support. Now it is possible to use hunspell dictionaries with complex affix files, which were not supported in earlier versions.

Some hunspell dictionaries are included in the distribution. See Section E.24.3.3 below.

#### **E.24.3.2. Portability improvements**

- Use `libcicu` instead of system specific locale handling functions. This ensures same collating order on all platforms Based on patch by Palle Girgensohn <http://people.freebsd.org/~girgen/postgresql-icu/README.html>, ported to 9.5 and abbreviated sort key support added by Teodor Sigaev.

#### **E.24.3.3. Additional Modules**

- `pageinspect` extension now can extract tuple data, not only metainformation.
- `pg_trgm` contrib module, which allows to do fuzzy string comparisons, now supports substring searches.
- `sr_plan` contrib module, which allows to save execution plan and force use of saved, known-good plan instead of computing new one each time.
- `dump_stat` contrib module. This module allows to dump table statistics and restore it, thus eliminate need to run `VACUUM ANALYZE` after restoration of base or server upgrade
- Several hunspell dictionaries for full-text search are now included as contrib modules and can be easily installed into the database using `CREATE EXTENSION` command.

## **E.25. Release 10.1**

**Release date:** 2017-11-09

This release contains a variety of fixes from 10.0. For information about new features in major release 10, see Section E.26.

### **E.25.1. Migration to Version 10.1**

A dump/restore is not required for those running 10.X.

However, if you use BRIN indexes, see the fourth changelog entry below.

### **E.25.2. Changes**

- Ensure that `INSERT ... ON CONFLICT DO UPDATE` checks table permissions and RLS policies in all cases (Dean Rasheed)

The update path of `INSERT ... ON CONFLICT DO UPDATE` requires `SELECT` permission on the columns of the arbiter index, but it failed to check for that in the case of an arbiter specified by

constraint name. In addition, for a table with row level security enabled, it failed to check updated rows against the table's `SELECT` policies (regardless of how the arbiter index was specified). (CVE-2017-15099)

- Fix crash due to rowtype mismatch in `json{b}_populate_recordset()` (Michael Paquier, Tom Lane)

These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn't, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix BRIN index summarization to handle concurrent table extension correctly (Álvaro Herrera)

Previously, a race condition allowed some table rows to be omitted from the index. It may be necessary to reindex existing BRIN indexes to recover from past occurrences of this problem.

- Fix possible failures during concurrent updates of a BRIN index (Tom Lane)

These race conditions could result in errors like “invalid index offnum” or “inconsistent range map”.

- Prevent logical replication from setting non-replicated columns to nulls when replicating an `UPDATE` (Petr Jelinek)
- Fix logical replication to fire `BEFORE ROW DELETE` triggers when expected (Masahiko Sawada)

Previously, that failed to happen unless the table also had a `BEFORE ROW UPDATE` trigger.

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)
- Ignore CTEs when looking up the target table for `INSERT/UPDATE/DELETE`, and prevent matching schema-qualified target table names to trigger transition table names (Thomas Munro)

This restores the pre-v10 behavior for CTEs attached to DML commands.

- Avoid evaluating an aggregate function's argument expression(s) at rows where its `FILTER` test fails (Tom Lane)

This restores the pre-v10 (and SQL-standard) behavior.

- Fix incorrect query results when multiple `GROUPING SETS` columns contain the same simple variable (Tom Lane)
- Fix query-lifespan memory leakage while evaluating a set-returning function in a `SELECT`'s target list (Tom Lane)
- Allow parallel execution of prepared statements with generic plans (Amit Kapila, Kuntal Ghosh)
- Fix incorrect parallelization decisions for nested queries (Amit Kapila, Kuntal Ghosh)
- Fix parallel query handling to not fail when a recently-used role is dropped (Amit Kapila)
- Fix crash in parallel execution of a bitmap scan having a `BitmapAnd` plan node below a `BitmapOr` node (Dilip Kumar)

- Fix `json_build_array()`, `json_build_object()`, and their `jsonb` equivalents to handle explicit `VARIADIC` arguments correctly (Michael Paquier)
- Fix `autovacuum`'s “work item” logic to prevent possible crashes and silent loss of work items (Álvaro Herrera)
- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range's subtype has hash support. This does not affect any of the built-in range types, since they're all hashable anyway.

- Correctly ignore `RelabelType` expression nodes when examining functional-dependency statistics (David Rowley)

This allows, e.g., extended statistics on `varchar` columns to be used properly.

- Prevent sharing transition states between ordered-set aggregates (David Rowley)

This causes a crash with the built-in ordered-set aggregates, and probably with user-written ones as well. `v11` and later will include provisions for dealing with such cases safely, but in released branches, just disable the optimization.

- Prevent `idle_in_transaction_session_timeout` from being ignored when a `statement_timeout` occurred earlier (Lukas Fittl)
- Fix low-probability loss of `NOTIFY` messages due to `XID` wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Reduce the frequency of data flush requests during bulk file copies to avoid performance problems on `macOS`, particularly with its new `APFS` file system (Tom Lane)
- Allow `COPY`'s `FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)

This case was unintentionally broken by a previous bug fix.

- Fix `AggGetAggref()` to return the correct `Aggref` nodes to aggregate final functions whose transition calculations have been merged (Tom Lane)
- Fix insufficient schema-qualification in some new queries in `pg_dump` and `psql` (Vitaly Burovoy, Tom Lane, Noah Misch)
- Avoid use of `@>` operator in `psql`'s queries for `\d` (Tom Lane)

This prevents problems when the `parray_gin` extension is installed, since that defines a conflicting operator.

- Fix `pg_basebackup`'s matching of tablespace paths to canonicalize both paths before comparing (Michael Paquier)

This is particularly helpful on `Windows`.

- Fix `libpq` to not require user's home directory to exist (Tom Lane)

In `v10`, failure to find the home directory while trying to read `~/ .pgpass` was treated as a hard error, but it should just cause that file to not be found. Both `v10` and previous release branches made

the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- In `ecpglib`, correctly handle backslashes in string literals depending on whether `standard_conforming_strings` is set (Tsunakawa Takayuki)
- Make `ecpglib`'s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Fix missing `temp-install` prerequisites for `check`-like Make targets (Noah Misch)

Some non-default test procedures that are meant to work like `make check` failed to ensure that the temporary installation was up to date.

- Update time zone data files to `tzdata` release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.
- In the documentation, restore HTML anchors to being upper-case strings (Peter Eisentraut)

Due to a toolchain change, the 10.0 user manual had lower-case strings for intrapage anchors, thus breaking some external links into our website documentation. Return to our previous convention of using upper-case strings.

## E.26. Release 10

**Release date:** 2017-10-05

### E.26.1. Overview

Major enhancements in PostgreSQL 10 include:

- Logical replication using `publish/subscribe`
- Declarative table partitioning
- Improved query parallelism
- Significant general performance improvements
- Stronger password authentication based on SCRAM-SHA-256
- Improved monitoring and control

The above items are explained in more detail in the sections below.

### E.26.2. Migration to Version 10

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 10 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Hash indexes must be rebuilt after `pg_upgrade`-ing from any previous major PostgreSQL version (Mithun Cy, Robert Haas, Amit Kapila)

Major hash index improvements necessitated this requirement. `pg_upgrade` will create a script to assist with this.

- Rename write-ahead log directory `pg_xlog` to `pg_wal`, and rename transaction status directory `pg_clog` to `pg_xact` (Michael Paquier)

Users have occasionally thought that these directories contained only inessential log files, and proceeded to remove write-ahead log files or transaction status files manually, causing irrecoverable data loss. These name changes are intended to discourage such errors in future.

- Rename SQL functions, tools, and options that reference “xlog” to “wal” (Robert Haas)

For example, `pg_switch_xlog()` becomes `pg_switch_wal()`, `pg_receivexlog` becomes `pg_receivewal`, and `--xlogdir` becomes `--waldir`. This is for consistency with the change of the `pg_xlog` directory name; in general, the “xlog” terminology is no longer used in any user-facing places.

- Rename WAL-related functions and views to use `lsn` instead of `location` (David Rowley)

There was previously an inconsistent mixture of the two terminologies.

- Change the implementation of set-returning functions appearing in a query's `SELECT` list (Andres Freund)

Set-returning functions are now evaluated before evaluation of scalar expressions in the `SELECT` list, much as though they had been placed in a `LATERAL FROM`-clause item. This allows saner semantics for cases where multiple set-returning functions are present. If they return different numbers of rows, the shorter results are extended to match the longest result by adding nulls. Previously the results were cycled until they all terminated at the same time, producing a number of rows equal to the least common multiple of the functions' periods. In addition, set-returning functions are now disallowed within `CASE` and `COALESCE` constructs. For more information see Section 38.4.8.

- Use standard row constructor syntax in `UPDATE ... SET (column_list) = row_constructor` (Tom Lane)

The *row\_constructor* can now begin with the keyword `ROW`; previously that had to be omitted. If just one column name appears in the *column\_list*, then the *row\_constructor* now must use the `ROW` keyword, since otherwise it is not a valid row constructor but just a parenthesized expression. Also, an occurrence of *table\_name.\** within the *row\_constructor* is now expanded into multiple columns, as occurs in other uses of *row\_constructors*.

- When `ALTER TABLE ... ADD PRIMARY KEY` marks columns `NOT NULL`, that change now propagates to inheritance child tables as well (Michael Paquier)
- Prevent statement-level triggers from firing more than once per statement (Tom Lane)

Cases involving writable CTEs updating the same table updated by the containing statement, or by another writable CTE, fired `BEFORE STATEMENT` or `AFTER STATEMENT` triggers more than once. Also, if there were statement-level triggers on a table affected by a foreign key enforcement action (such as `ON DELETE CASCADE`), they could fire more than once per outer SQL statement. This is contrary to the SQL standard, so change it.

- Move sequences' metadata fields into a new `pg_sequence` system catalog (Peter Eisentraut)

A sequence relation now stores only the fields that can be modified by `nextval()`, that is `last_value`, `log_cnt`, and `is_called`. Other sequence properties, such as the starting value and increment, are kept in a corresponding row of the `pg_sequence` catalog. `ALTER SEQUENCE` updates are now fully transactional, implying that the sequence is locked until commit. The `nextval()` and `setval()` functions remain nontransactional.

The main incompatibility introduced by this change is that selecting from a sequence relation now returns only the three fields named above. To obtain the sequence's other properties, applications must look into `pg_sequence`. The new system view `pg_sequences` can also be used for this purpose; it provides column names that are more compatible with existing code.

The output of `psql's \d` command for a sequence has been redesigned, too.

- Make `pg_basebackup` stream the WAL needed to restore the backup by default (Magnus Hagander)

This changes `pg_basebackup's -X/--wal-method` default to `stream`. An option value `none` has been added to reproduce the old behavior. The `pg_basebackup` option `-x` has been removed (instead, use `-X fetch`).

- Change how logical replication uses `pg_hba.conf` (Peter Eisentraut)

In previous releases, a logical replication connection required the `replication` keyword in the database column. As of this release, logical replication matches a normal entry with a database name or keywords such as `all`. Physical replication continues to use the `replication` keyword. Since built-in logical replication is new in this release, this change only affects users of third-party logical replication plugins.

- Make all `pg_ctl` actions wait for completion by default (Peter Eisentraut)

Previously some `pg_ctl` actions didn't wait for completion, and required the use of `-w` to do so.

- Change the default value of the `log_directory` server parameter from `pg_log` to `log` (Andreas Karlsson)
- Add configuration option `ssl_dh_params_file` to specify file name for custom OpenSSL DH parameters (Heikki Linnakangas)

This replaces the hardcoded, undocumented file name `dh1024.pem`. Note that `dh1024.pem` is no longer examined by default; you must set this option if you want to use custom DH parameters.

- Increase the size of the default DH parameters used for OpenSSL ephemeral DH ciphers to 2048 bits (Heikki Linnakangas)

The size of the compiled-in DH parameters has been increased from 1024 to 2048 bits, making DH key exchange more resistant to brute-force attacks. However, some old SSL implementations, notably some revisions of Java Runtime Environment version 6, will not accept DH parameters longer than 1024 bits, and hence will not be able to connect over SSL. If it's necessary to support such old clients, you can use custom 1024-bit DH parameters instead of the compiled-in defaults. See `ssl_dh_params_file`.

- Remove the ability to store unencrypted passwords on the server (Heikki Linnakangas)

The `password_encryption` server parameter no longer supports `off` or `plain`. The `UNENCRYPTED` option is no longer supported in `CREATE/ALTER USER ... PASSWORD`. Similarly, the `--unencrypted` option has been removed from `createuser`. Unencrypted passwords migrated from older versions will be stored encrypted in this release. The default setting for `password_encryption` is still `md5`.

- Add `min_parallel_table_scan_size` and `min_parallel_index_scan_size` server parameters to control parallel queries (Amit Kapila, Robert Haas)

These replace `min_parallel_relation_size`, which was found to be too generic.

- Don't downcase unquoted text within `shared_preload_libraries` and related server parameters (QL Zhuo)

These settings are really lists of file names, but they were previously treated as lists of SQL identifiers, which have different parsing rules.

- Remove `sql_inheritance` server parameter (Robert Haas)

Changing this setting from the default value caused queries referencing parent tables to not include child tables. The SQL standard requires them to be included, however, and this has been the default since PostgreSQL 7.1.

- Allow multi-dimensional arrays to be passed into PL/Python functions, and returned as nested Python lists (Alexey Grishchenko, Dave Cramer, Heikki Linnakangas)

This feature requires a backwards-incompatible change to the handling of arrays of composite types in PL/Python. Previously, you could return an array of composite values by writing, e.g., `[[col1, col2], [col1, col2]]`; but now that is interpreted as a two-dimensional array. Composite types in arrays must now be written as Python tuples, not lists, to resolve the ambiguity; that is, write `[(col1, col2), (col1, col2)]` instead.

- Remove PL/Tcl's "module" auto-loading facility (Tom Lane)

This functionality has been replaced by new server parameters `pltcl.start_proc` and `pltclu.start_proc`, which are easier to use and more similar to features available in other PLs.

- Remove `pg_dump/pg_dumpall` support for dumping from pre-8.0 servers (Tom Lane)

Users needing to dump from pre-8.0 servers will need to use dump programs from PostgreSQL 9.6 or earlier. The resulting output should still load successfully into newer servers.

- Remove support for floating-point timestamps and intervals (Tom Lane)

This removes `configure`'s `--disable-integer-datetimes` option. Floating-point timestamps have few advantages and have not been the default since PostgreSQL 8.3.

- Remove server support for client/server protocol version 1.0 (Tom Lane)

This protocol hasn't had client support since PostgreSQL 6.3.

- Remove `contrib/tsearch2` module (Robert Haas)

This module provided compatibility with the version of full text search that shipped in pre-8.3 PostgreSQL releases.

- Remove `createlang` and `droplang` command-line applications (Peter Eisentraut)

These had been deprecated since PostgreSQL 9.1. Instead, use `CREATE EXTENSION` and `DROP EXTENSION` directly.

- Remove support for version-0 function calling conventions (Andres Freund)

Extensions providing C-coded functions must now conform to version 1 calling conventions. Version 0 has been deprecated since 2001.

## E.26.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 10 and the previous major release.

### E.26.3.1. Server

#### E.26.3.1.1. Parallel Queries

- Support parallel B-tree index scans (Rahila Syed, Amit Kapila, Robert Haas, Rafia Sabih)

This change allows B-tree index pages to be searched by separate parallel workers.

- Support parallel bitmap heap scans (Dilip Kumar)

This allows a single index scan to dispatch parallel workers to process different areas of the heap.

- Allow merge joins to be performed in parallel (Dilip Kumar)
- Allow non-correlated subqueries to be run in parallel (Amit Kapila)
- Improve ability of parallel workers to return pre-sorted data (Rushabh Lathia)
- Increase parallel query usage in procedural language functions (Robert Haas, Rafia Sabih)
- Add `max_parallel_workers` server parameter to limit the number of worker processes that can be used for query parallelism (Julien Rouhaud)

This parameter can be set lower than `max_worker_processes` to reserve worker processes for purposes other than parallel queries.

#### E.26.3.1.2. Indexes

- Add write-ahead logging support to hash indexes (Amit Kapila)

This makes hash indexes crash-safe and replicatable. The former warning message about their use is removed.

- Improve hash index performance (Amit Kapila, Mithun Cy, Ashutosh Sharma)
- Add SP-GiST index support for `INET` and `CIDR` data types (Emre Hasegeli)
- Add option to allow BRIN index summarization to happen more aggressively (Álvaro Herrera)

A new `CREATE INDEX` option enables auto-summarization of the previous BRIN page range when a new page range is created.

- Add functions to remove and re-add BRIN summarization for BRIN index ranges (Álvaro Herrera)

The new SQL function `brin_summarize_range()` updates BRIN index summarization for a specified range and `brin_desummarize_range()` removes it. This is helpful to update summarization of a range that is now smaller due to `UPDATES` and `DELETES`.

- Improve accuracy in determining if a BRIN index scan is beneficial (David Rowley, Emre Hasegeli)
- Allow faster GiST inserts and updates by reusing index space more efficiently (Andrey Borodin)
- Reduce page locking during vacuuming of GIN indexes (Andrey Borodin)

#### **E.26.3.1.3. Locking**

- Reduce locking required to change table parameters (Simon Riggs, Fabrízio Mello)

For example, changing a table's `effective_io_concurrency` setting can now be done with a more lightweight lock.

- Allow tuning of predicate lock promotion thresholds (Dagfinn Ilmari Mannsåker)

Lock promotion can now be controlled through two new server parameters, `max_pred_locks_per_relation` and `max_pred_locks_per_page`.

#### **E.26.3.1.4. Optimizer**

- Add multi-column optimizer statistics to compute the correlation ratio and number of distinct values (Tomas Vondra, David Rowley, Álvaro Herrera)

New commands are `CREATE STATISTICS`, `ALTER STATISTICS`, and `DROP STATISTICS`. This feature is helpful in estimating query memory usage and when combining the statistics from individual columns.

- Improve performance of queries affected by row-level security restrictions (Tom Lane)

The optimizer now has more knowledge about where it can place RLS filter conditions, allowing better plans to be generated while still enforcing the RLS conditions safely.

#### **E.26.3.1.5. General Performance**

- Speed up aggregate functions that calculate a running sum using `numeric`-type arithmetic, including some variants of `SUM()`, `AVG()`, and `STDDEV()` (Heikki Linnakangas)
- Improve performance of character encoding conversions by using radix trees (Kyotaro Horiguchi, Heikki Linnakangas)
- Reduce expression evaluation overhead during query execution, as well as plan node calling overhead (Andres Freund)

This is particularly helpful for queries that process many rows.

- Allow hashed aggregation to be used with grouping sets (Andrew Gierth)
- Use uniqueness guarantees to optimize certain join types (David Rowley)

- Improve sort performance of the `macaddr` data type (Brandur Leach)
- Reduce statistics tracking overhead in sessions that reference many thousands of relations (Alexander Alekseev)

#### **E.26.3.1.6. Monitoring**

- Allow explicit control over `EXPLAIN`'s display of planning and execution time (Ashutosh Bapat)

By default planning and execution time are displayed by `EXPLAIN ANALYZE` and are not displayed in other cases. The new `EXPLAIN` option `SUMMARY` allows explicit control of this.

- Add default monitoring roles (Dave Page)

New roles `pg_monitor`, `pg_read_all_settings`, `pg_read_all_stats`, and `pg_stat_scan_tables` allow simplified permission configuration.

- Properly update the statistics collector during `REFRESH MATERIALIZED VIEW` (Jim Mlodgenski)

#### **E.26.3.1.6.1. Logging**

- Change the default value of `log_line_prefix` to include current timestamp (with milliseconds) and the process ID in each line of postmaster log output (Christoph Berg)

The previous default was an empty prefix.

- Add functions to return the log and WAL directory contents (Dave Page)

The new functions are `pg_ls_logdir()` and `pg_ls_waldir()` and can be executed by non-superusers with the proper permissions.

- Add function `pg_current_logfile()` to read logging collector's current stderr and csvlog output file names (Gilles Darold)
- Report the address and port number of each listening socket in the server log during postmaster startup (Tom Lane)

Also, when logging failure to bind a listening socket, include the specific address we attempted to bind to.

- Reduce log chatter about the starting and stopping of launcher subprocesses (Tom Lane)

These are now `DEBUG1`-level messages.

- Reduce message verbosity of lower-numbered debug levels controlled by `log_min_messages` (Robert Haas)

This also changes the verbosity of `client_min_messages` debug levels.

#### **E.26.3.1.6.2. `pg_stat_activity`**

- Add `pg_stat_activity` reporting of low-level wait states (Michael Paquier, Robert Haas, Rushabh Lathia)

This change enables reporting of numerous low-level wait conditions, including latch waits, file reads/writes/fsyncs, client reads/writes, and synchronous replication.

- Show auxiliary processes, background workers, and walsender processes in `pg_stat_activity` (Kuntal Ghosh, Michael Paquier)

This simplifies monitoring. A new column `backend_type` identifies the process type.

- Allow `pg_stat_activity` to show the SQL query being executed by parallel workers (Rafia Sabih)
- Rename `pg_stat_activity.wait_event_type` values `LWLockTranche` and `LWLockNamed` to `LWLock` (Robert Haas)

This makes the output more consistent.

#### **E.26.3.1.7. Authentication**

- Add SCRAM-SHA-256 support for password negotiation and storage (Michael Paquier, Heikki Linnakangas)

This provides better security than the existing `md5` negotiation and storage method.

- Change the `password_encryption` server parameter from `boolean` to `enum` (Michael Paquier)

This was necessary to support additional password hashing options.

- Add view `pg_hba_file_rules` to display the contents of `pg_hba.conf` (Haribabu Kommi)

This shows the file contents, not the currently active settings.

- Support multiple RADIUS servers (Magnus Hagander)

All the RADIUS related parameters are now plural and support a comma-separated list of servers.

#### **E.26.3.1.8. Server Configuration**

- Allow SSL configuration to be updated during configuration reload (Andreas Karlsson, Tom Lane)

This allows SSL to be reconfigured without a server restart, by using `pg_ctl reload`, `SELECT pg_reload_conf()`, or sending a `SIGHUP` signal. However, reloading the SSL configuration does not work if the server's SSL key requires a passphrase, as there is no way to re-prompt for the passphrase. The original configuration will apply for the life of the postmaster in that case.

- Make the maximum value of `bgwriter_lru_maxpages` effectively unlimited (Jim Nasby)

#### **E.26.3.1.9. Reliability**

- After creating or unlinking files, perform an `fsync` on their parent directory (Michael Paquier)

This reduces the risk of data loss after a power failure.

##### **E.26.3.1.9.1. Write-Ahead Log (WAL)**

- Prevent unnecessary checkpoints and WAL archiving on otherwise-idle systems (Michael Paquier)
- Add `wal_consistency_checking` server parameter to add details to WAL that can be sanity-checked on the standby (Kuntal Ghosh, Robert Haas)

Any sanity-check failure generates a fatal error on the standby.

- Increase the maximum configurable WAL segment size to one gigabyte (Beena Emerson)

A larger WAL segment size allows for fewer `archive_command` invocations and fewer WAL files to manage.

#### **E.26.3.2. Replication and Recovery**

- Add the ability to logically replicate tables to standby servers (Petr Jelinek)

Logical replication allows more flexibility than physical replication does, including replication between different major versions of PostgreSQL and selective replication.

- Allow waiting for commit acknowledgement from standby servers irrespective of the order they appear in `synchronous_standby_names` (Masahiko Sawada)

Previously the server always waited for the active standbys that appeared first in `synchronous_standby_names`. The new `synchronous_standby_names` keyword `ANY` allows waiting for any number of standbys irrespective of their ordering. This is known as quorum commit.

- Reduce configuration changes necessary to perform streaming backup and replication (Magnus Hagander, Dang Minh Huong)

Specifically, the defaults were changed for `wal_level`, `max_wal_senders`, `max_replication_slots`, and `hot_standby` to make them suitable for these usages out-of-the-box.

- Enable replication from localhost connections by default in `pg_hba.conf` (Michael Paquier)

Previously `pg_hba.conf`'s replication connection lines were commented out by default. This is particularly useful for `pg_basebackup`.

- Add columns to `pg_stat_replication` to report replication delay times (Thomas Munro)

The new columns are `write_lag`, `flush_lag`, and `replay_lag`.

- Allow specification of the recovery stopping point by Log Sequence Number (LSN) in `recovery.conf` (Michael Paquier)

Previously the stopping point could only be selected by timestamp or XID.

- Allow users to disable `pg_stop_backup()`'s waiting for all WAL to be archived (David Steele)

An optional second argument to `pg_stop_backup()` controls that behavior.

- Allow creation of temporary replication slots (Petr Jelinek)

Temporary slots are automatically removed on session exit or error.

- Improve performance of hot standby replay with better tracking of Access Exclusive locks (Simon Riggs, David Rowley)
- Speed up two-phase commit recovery performance (Stas Kelvich, Nikhil Sontakke, Michael Paquier)

### E.26.3.3. Queries

- Add `XMLTABLE` function that converts XML-formatted data into a row set (Pavel Stehule, Álvaro Herrera)
- Fix regular expressions' character class handling for large character codes, particularly Unicode characters above `U+7FF` (Tom Lane)

Previously, such characters were never recognized as belonging to locale-dependent character classes such as `[:alpha:]`.

### E.26.3.4. Utility Commands

- Add table partitioning syntax that automatically creates partition constraints and handles routing of tuple insertions and updates (Amit Langote)

The syntax supports range and list partitioning.

- Add `AFTER` trigger transition tables to record changed rows (Kevin Grittner, Thomas Munro)

Transition tables are accessible from triggers written in server-side languages.

- Allow restrictive row-level security policies (Stephen Frost)

Previously all security policies were permissive, meaning that any matching policy allowed access. A restrictive policy must match for access to be granted. These policy types can be combined.

- When creating a foreign-key constraint, check for `REFERENCES` permission on only the referenced table (Tom Lane)

Previously `REFERENCES` permission on the referencing table was also required. This appears to have stemmed from a misreading of the SQL standard. Since creating a foreign key (or any other type of)

constraint requires ownership privilege on the constrained table, additionally requiring `REFERENCES` permission seems rather pointless.

- Allow default permissions on schemas (Matheus Oliveira)

This is done using the `ALTER DEFAULT PRIVILEGES` command.

- Add `CREATE SEQUENCE AS` command to create a sequence matching an integer data type (Peter Eisentraut)

This simplifies the creation of sequences matching the range of base columns.

- Allow `COPY view FROM source` on views with `INSTEAD INSERT` triggers (Haribabu Kommi)

The triggers are fed the data rows read by `COPY`.

- Allow the specification of a function name without arguments in DDL commands, if it is unique (Peter Eisentraut)

For example, allow `DROP FUNCTION` on a function name without arguments if there is only one function with that name. This behavior is required by the SQL standard.

- Allow multiple functions, operators, and aggregates to be dropped with a single `DROP` command (Peter Eisentraut)
- Support `IF NOT EXISTS` in `CREATE SERVER`, `CREATE USER MAPPING`, and `CREATE COLLATION` (Anastasia Lubennikova, Peter Eisentraut)
- Make `VACUUM VERBOSE` report the number of skipped frozen pages and oldest xmin (Masahiko Sawada, Simon Riggs)

This information is also included in `log_autovacuum_min_duration` output.

- Improve speed of `VACUUM`'s removal of trailing empty heap pages (Claudio Freire, Álvaro Herrera)

### E.26.3.5. Data Types

- Add full text search support for `JSON` and `JSONB` (Dmitry Dolgov)

The functions `ts_headline()` and `to_tsvector()` can now be used on these data types.

- Add support for EUI-64 MAC addresses, as a new data type `macaddr8` (Haribabu Kommi)

This complements the existing support for EUI-48 MAC addresses (type `macaddr`).

- Add identity columns for assigning a numeric value to columns on insert (Peter Eisentraut)

These are similar to `SERIAL` columns, but are SQL standard compliant.

- Allow `ENUM` values to be renamed (Dagfinn Ilmari Mannsåker)

This uses the syntax `ALTER TYPE ... RENAME VALUE`.

- Properly treat array pseudotypes (`anyarray`) as arrays in `to_json()` and `to_jsonb()` (Andrew Dunstan)

Previously columns declared as `anyarray` (particularly those in the `pg_stats` view) were converted to `JSON` strings rather than arrays.

- Add operators for multiplication and division of `money` values with `int8` values (Peter Eisentraut)

Previously such cases would result in converting the `int8` values to `float8` and then using the `money-and-float8` operators. The new behavior avoids possible precision loss. But note that division of `money` by `int8` now truncates the quotient, like other integer-division cases, while the previous behavior would have rounded.

- Check for overflow in the `money` type's input function (Peter Eisentraut)

### E.26.3.6. Functions

- Add simplified `regexp_match()` function (Emre Hasegeli)

This is similar to `regexp_matches()`, but it only returns results from the first match so it does not need to return a set, making it easier to use for simple cases.

- Add a version of `jsonb`'s delete operator that takes an array of keys to delete (Magnus Hagander)
- Make `json_populate_record()` and related functions process JSON arrays and objects recursively (Nikita Glukhov)

With this change, array-type fields in the destination SQL type are properly converted from JSON arrays, and composite-type fields are properly converted from JSON objects. Previously, such cases would fail because the text representation of the JSON value would be fed to `array_in()` or `record_in()`, and its syntax would not match what those input functions expect.

- Add function `txid_current_if_assigned()` to return the current transaction ID or NULL if no transaction ID has been assigned (Craig Ringer)

This is different from `txid_current()`, which always returns a transaction ID, assigning one if necessary. Unlike that function, this function can be run on standby servers.

- Add function `txid_status()` to check if a transaction was committed (Craig Ringer)

This is useful for checking after an abrupt disconnection whether your previous transaction committed and you just didn't receive the acknowledgement.

- Allow `make_date()` to interpret negative years as BC years (Álvaro Herrera)
- Make `to_timestamp()` and `to_date()` reject out-of-range input fields (Artur Zakirov)

For example, previously `to_date('2009-06-40', 'YYYY-MM-DD')` was accepted and returned 2009-07-10. It will now generate an error.

### E.26.3.7. Server-Side Languages

- Allow PL/Python's `cursor()` and `execute()` functions to be called as methods of their plan-object arguments (Peter Eisentraut)

This allows a more object-oriented programming style.

- Allow PL/pgSQL's `GET DIAGNOSTICS` statement to retrieve values into array elements (Tom Lane)

Previously, a syntactic restriction prevented the target variable from being an array element.

#### E.26.3.7.1. PL/Tcl

- Allow PL/Tcl functions to return composite types and sets (Karl Lehenbauer)
- Add a subtransaction command to PL/Tcl (Victor Wagner)

This allows PL/Tcl queries to fail without aborting the entire function.

- Add server parameters `pltcl.start_proc` and `pltclu.start_proc`, to allow initialization functions to be called on PL/Tcl startup (Tom Lane)

### E.26.3.8. Client Interfaces

- Allow specification of multiple host names or addresses in `libpq` connection strings and URIs (Robert Haas, Heikki Linnakangas)

`libpq` will connect to the first responsive server in the list.

- Allow `libpq` connection strings and URIs to request a read/write host, that is a master server rather than a standby server (Victor Wagner, Mithun Cy)

This is useful when multiple host names are specified. It is controlled by libpq connection parameter `target_session_attrs`.

- Allow the password file name to be specified as a libpq connection parameter (Julian Markwort)

Previously this could only be specified via an environment variable.

- Add function `PQencryptPasswordConn()` to allow creation of more types of encrypted passwords on the client side (Michael Paquier, Heikki Linnakangas)

Previously only MD5-encrypted passwords could be created using `PQencryptPassword()`. This new function can also create SCRAM-SHA-256-encrypted passwords.

- Change ecpg preprocessor version from 4.12 to 10 (Tom Lane)

Henceforth the ecpg version will match the PostgreSQL distribution version number.

### E.26.3.9. Client Applications

- Add conditional branch support to psql (Corey Huinker)

This feature adds psql meta-commands `\if`, `\elif`, `\else`, and `\endif`. This is primarily helpful for scripting.

- Add psql `\gx` meta-command to execute (`\g`) a query in expanded mode (`\x`) (Christoph Berg)
- Expand psql variable references in backtick-executed strings (Tom Lane)

This is particularly useful in the new psql conditional branch commands.

- Prevent psql's special variables from being set to invalid values (Daniel Vérité, Tom Lane)

Previously, setting one of psql's special variables to an invalid value silently resulted in the default behavior. `\set` on a special variable now fails if the proposed new value is invalid. As a special exception, `\set` with an empty or omitted new value, on a boolean-valued special variable, still has the effect of setting the variable to `on`; but now it actually acquires that value rather than an empty string. `\unset` on a special variable now explicitly sets the variable to its default value, which is also the value it acquires at startup. In sum, a control variable now always has a displayable value that reflects what psql is actually doing.

- Add variables showing server version and psql version (Fabien Coelho)
- Improve psql's `\d` (display relation) and `\dD` (display domain) commands to show collation, nullable, and default properties in separate columns (Peter Eisentraut)

Previously they were shown in a single “Modifiers” column.

- Make the various `\d` commands handle no-matching-object cases more consistently (Daniel Gustafsson)

They now all print the message about that to `stderr`, not `stdout`, and the message wording is more consistent.

- Improve psql's tab completion (Jeff Janes, Ian Barwick, Andreas Karlsson, Sehrope Sarkuni, Thomas Munro, Kevin Grittner, Dagfinn Ilmari Mannsåker)

- Add `pgbench` option `--log-prefix` to control the log file prefix (Masahiko Sawada)
- Allow `pgbench`'s meta-commands to span multiple lines (Fabien Coelho)

A meta-command can now be continued onto the next line by writing backslash-return.

- Remove restriction on placement of `-M` option relative to other command line options (Tom Lane)

### E.26.3.10. Server Applications

- Add `pg_receivewal` option `-z/--compress` to specify compression (Michael Paquier)
- Add `pg_recvlogical` option `--endpos` to specify the ending position (Craig Ringer)

This complements the existing `--startpos` option.

- Rename `initdb` options `--noclean` and `--nosync` to be spelled `--no-clean` and `--no-sync` (Vik Fearing, Peter Eisentraut)

The old spellings are still supported.

#### E.26.3.10.1. `pg_dump`, `pg_dumpall`, `pg_restore`

- Allow `pg_restore` to exclude schemas (Michael Banck)

This adds a new `-N/--exclude-schema` option.

- Add `--no-blobs` option to `pg_dump` (Guillaume Lelarge)

This suppresses dumping of large objects.

- Add `pg_dumpall` option `--no-role-passwords` to omit role passwords (Robins Tharakan, Simon Riggs)

This allows use of `pg_dumpall` by non-superusers; without this option, it fails due to inability to read passwords.

- Support using synchronized snapshots when dumping from a standby server (Petr Jelinek)
- Issue `fsync()` on the output files generated by `pg_dump` and `pg_dumpall` (Michael Paquier)

This provides more security that the output is safely stored on disk before the program exits. This can be disabled with the new `--no-sync` option.

- Allow `pg_basebackup` to stream write-ahead log in tar mode (Magnus Hagander)

The WAL will be stored in a separate tar file from the base backup.

- Make `pg_basebackup` use temporary replication slots (Magnus Hagander)

Temporary replication slots will be used by default when `pg_basebackup` uses WAL streaming with default options.

- Be more careful about `fsync`'ing in all required places in `pg_basebackup` and `pg_receivewal` (Michael Paquier)
- Add `pg_basebackup` option `--no-sync` to disable `fsync` (Michael Paquier)
- Improve `pg_basebackup`'s handling of which directories to skip (David Steele)

- Add `wait` option for `pg_ctl`'s `promote` operation (Peter Eisentraut)
- Add long options for `pg_ctl` `wait` (`--wait`) and `no-wait` (`--no-wait`) (Vik Fearing)
- Add long option for `pg_ctl` server options (`--options`) (Peter Eisentraut)
- Make `pg_ctl start --wait` detect server-ready by watching `postmaster.pid`, not by attempting connections (Tom Lane)

The `postmaster` has been changed to report its ready-for-connections status in `postmaster.pid`, and `pg_ctl` now examines that file to detect whether startup is complete. This is more efficient and reliable than the old method, and it eliminates `postmaster` log entries about rejected connection attempts during startup.

- Reduce `pg_ctl`'s reaction time when waiting for `postmaster` start/stop (Tom Lane)

`pg_ctl` now probes ten times per second when waiting for a postmaster state change, rather than once per second.

- Ensure that `pg_ctl` exits with nonzero status if an operation being waited for does not complete within the timeout (Peter Eisentraut)

The `start` and `promote` operations now return exit status 1, not 0, in such cases. The `stop` operation has always done that.

### E.26.3.11. Source Code

- Change to two-part release version numbering (Peter Eisentraut, Tom Lane)

Release numbers will now have two parts (e.g., 10.1) rather than three (e.g., 9.6.3). Major versions will now increase just the first number, and minor releases will increase just the second number. Release branches will be referred to by single numbers (e.g., 10 rather than 9.6). This change is intended to reduce user confusion about what is a major or minor release of PostgreSQL.

- Improve behavior of `pgindent` (Piotr Stefaniak, Tom Lane)

We have switched to a new version of `pg_bsd_indent` based on recent improvements made by the FreeBSD project. This fixes numerous small bugs that led to odd C code formatting decisions. Most notably, lines within parentheses (such as in a multi-line function call) are now uniformly indented to match the opening paren, even if that would result in code extending past the right margin.

- Allow the ICU library to optionally be used for collation support (Peter Eisentraut)

The ICU library has versioning that allows detection of collation changes between versions. It is enabled via configure option `--with-icu`. The default still uses the operating system's native collation library.

- Automatically mark all `PG_FUNCTION_INFO_V1` functions as `DLLEXPORT`-ed on Windows (Laurenz Albe)

If third-party code is using `extern` function declarations, they should also add `DLLEXPORT` markers to those declarations.

- Remove SPI functions `SPI_push()`, `SPI_pop()`, `SPI_push_conditional()`, `SPI_pop_conditional()`, and `SPI_restore_connection()` as unnecessary (Tom Lane)

Their functionality now happens automatically. There are now no-op macros by these names so that external modules don't need to be updated immediately, but eventually such calls should be removed.

A side effect of this change is that `SPI_palloc()` and allied functions now require an active SPI connection; they do not degenerate to simple `palloc()` if there is none. That previous behavior was not very useful and posed risks of unexpected memory leaks.

- Allow shared memory to be dynamically allocated (Thomas Munro, Robert Haas)
- Add slab-like memory allocator for efficient fixed-size allocations (Tomas Vondra)
- Use POSIX semaphores rather than SysV semaphores on Linux and FreeBSD (Tom Lane)

This avoids platform-specific limits on SysV semaphore usage.

- Improve support for 64-bit atomics (Andres Freund)
- Enable 64-bit atomic operations on ARM64 (Roman Shaposhnik)
- Switch to using `clock_gettime()`, if available, for duration measurements (Tom Lane)

`gettimeofday()` is still used if `clock_gettime()` is not available.

- Add more robust random number generators to be used for cryptographically secure uses (Magnus Hagander, Michael Paquier, Heikki Linnakangas)

If no strong random number generator can be found, configure will fail unless the `--disable-strong-random` option is used. However, with this option, `pgcrypto` functions requiring a strong random number generator will be disabled.

- Allow `WaitLatchOrSocket()` to wait for socket connection on Windows (Andres Freund)
- `tupconvert.c` functions no longer convert tuples just to embed a different composite-type OID in them (Ashutosh Bapat, Tom Lane)

The majority of callers don't care about the composite-type OID; but if the result tuple is to be used as a composite Datum, steps should be taken to make sure the correct OID is inserted in it.

- Remove SCO and Unixware ports (Tom Lane)
- Overhaul documentation build process (Alexander Lakhin)
- Use XSLT to build the PostgreSQL documentation (Peter Eisentraut)

Previously Jade, DSSSL, and JadeTex were used.

- Build HTML documentation using XSLT stylesheets by default (Peter Eisentraut)

### **E.26.3.12. Additional Modules**

- Allow `file_fdw` to read from program output as well as files (Corey Huinker, Adam Gomaa)
- In `postgres_fdw`, push aggregate functions to the remote server, when possible (Jeevan Chalke, Ashutosh Bapat)

This reduces the amount of data that must be passed from the remote server, and offloads aggregate computation from the requesting server.

- In `postgres_fdw`, push joins to the remote server in more cases (David Rowley, Ashutosh Bapat, Etsuro Fujita)
- Properly support `OID` columns in `postgres_fdw` tables (Etsuro Fujita)

Previously `OID` columns always returned zeros.

- Allow `btree_gist` and `btree_gin` to index enum types (Andrew Dunstan)

This allows enums to be used in exclusion constraints.

- Add indexing support to `btree_gist` for the `UUID` data type (Paul Jungwirth)
- Add `amcheck` which can check the validity of B-tree indexes (Peter Geoghegan)
- Show ignored constants as `$N` rather than `?` in `pg_stat_statements` (Lukas Fittl)
- Improve `cube`'s handling of zero-dimensional cubes (Tom Lane)

This also improves handling of `infinite` and `NaN` values.

- Allow `pg_buffercache` to run with fewer locks (Ivan Kartyshov)

This makes it less disruptive when run on production systems.

- Add `pgstattuple` function `pgstathashindex()` to view hash index statistics (Ashutosh Sharma)
- Use `GRANT` permissions to control `pgstattuple` function usage (Stephen Frost)

This allows DBAs to allow non-superusers to run these functions.

- Reduce locking when `pgstattuple` examines hash indexes (Amit Kapila)
- Add `pageinspect` function `page_checksum()` to show a page's checksum (Tomas Vondra)
- Add `pageinspect` function `bt_page_items()` to print page items from a page image (Tomas Vondra)
- Add hash index support to `pageinspect` (Jesper Pedersen, Ashutosh Sharma)

## E.26.4. Acknowledgments

The following individuals (in alphabetical order) have contributed to this release as patch authors, committers, reviewers, testers, or reporters of issues.

## E.27. Release 9.6.6

**Release date:** 2017-11-09

This release contains a variety of fixes from 9.6.5. For information about new features in the 9.6 major release, see Section E.33.

### E.27.1. Migration to Version 9.6.6

A dump/restore is not required for those running 9.6.X.

However, if you use BRIN indexes, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.6.4, see Section E.29.

### E.27.2. Changes

- Ensure that `INSERT ... ON CONFLICT DO UPDATE` checks table permissions and RLS policies in all cases (Dean Rasheed)

The update path of `INSERT ... ON CONFLICT DO UPDATE` requires `SELECT` permission on the columns of the arbiter index, but it failed to check for that in the case of an arbiter specified by constraint name. In addition, for a table with row level security enabled, it failed to check updated rows against the table's `SELECT` policies (regardless of how the arbiter index was specified). (CVE-2017-15099)

- Fix crash due to rowtype mismatch in `json{b}_populate_recordset()` (Michael Paquier, Tom Lane)

These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn't, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix BRIN index summarization to handle concurrent table extension correctly (Álvaro Herrera)

Previously, a race condition allowed some table rows to be omitted from the index. It may be necessary to reindex existing BRIN indexes to recover from past occurrences of this problem.

- Fix possible failures during concurrent updates of a BRIN index (Tom Lane)

These race conditions could result in errors like “invalid index offnum” or “inconsistent range map”.

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)
- Fix incorrect query results when multiple `GROUPING SETS` columns contain the same simple variable (Tom Lane)
- Fix incorrect parallelization decisions for nested queries (Amit Kapila, Kuntal Ghosh)
- Fix parallel query handling to not fail when a recently-used role is dropped (Amit Kapila)
- Fix `json_build_array()`, `json_build_object()`, and their `jsonb` equivalents to handle explicit `VARIADIC` arguments correctly (Michael Paquier)
- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range's subtype has hash support. This does not affect any of the built-in range types, since they're all hashable anyway.

- Correctly ignore `RelabelType` expression nodes when determining relation distinctness (David Rowley)

This allows the intended optimization to occur when a subquery has a result column of type `varchar`.

- Prevent sharing transition states between ordered-set aggregates (David Rowley)

This causes a crash with the built-in ordered-set aggregates, and probably with user-written ones as well. v11 and later will include provisions for dealing with such cases safely, but in released branches, just disable the optimization.

- Prevent `idle_in_transaction_session_timeout` from being ignored when a `statement_timeout` occurred earlier (Lukas Fittl)
- Fix low-probability loss of `NOTIFY` messages due to `XID` wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid `SIGBUS` crash on Linux when a DSM memory request exceeds the space available in `tmpfs` (Thomas Munro)
- Reduce the frequency of data flush requests during bulk file copies to avoid performance problems on macOS, particularly with its new APFS file system (Tom Lane)
- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Allow `COPY`'s `FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)

This case was unintentionally broken by a previous bug fix.

- Correctly restore the `umask` setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)
- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)
- Add missing cases in `GetCommandLogLevel()`, preventing errors when certain SQL commands are used while `log_statement` is set to `ddl` (Michael Paquier)
- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)
- Fix `AggGetAggref()` to return the correct `Aggref` nodes to aggregate final functions whose transition calculations have been merged (Tom Lane)
- Fix `pg_dump` to ensure that it emits `GRANT` commands in a valid order (Stephen Frost)
- Fix `pg_basebackup`'s matching of tablespace paths to canonicalize both paths before comparing (Michael Paquier)

This is particularly helpful on Windows.

- Fix `libpq` to not require user's home directory to exist (Tom Lane)

In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- Fix `libpq` to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)
- Fix `ecpg`'s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
- In `ecpglib`, correctly handle backslashes in string literals depending on whether `standard_conforming_strings` is set (Tsunakawa Takayuki)
- Make `ecpglib`'s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)

- Fix ecpg's regression tests to work reliably on Windows (Christian Ullrich, Michael Meskes)
- Fix missing temp-install prerequisites for `check`-like Make targets (Noah Misch)

Some non-default test procedures that are meant to work like `make check` failed to ensure that the temporary installation was up to date.

- Sync our copy of the timezone library with IANA release `tzcode2017c` (Tom Lane)

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to `tzdata` release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

## E.28. Release 9.6.5

**Release date:** 2017-08-31

This release contains a small number of fixes from 9.6.4. For information about new features in the 9.6 major release, see Section E.33.

### E.28.1. Migration to Version 9.6.5

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.4, see Section E.29.

### E.28.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in `psql`:

```
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
    SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
           CAST(grantee.rolname AS sql_identifier) AS grantee,
           CAST(current_database() AS sql_identifier) AS table_catalog,
           CAST(nc.nspname AS sql_identifier) AS table_schema,
           CAST(c.relname AS sql_identifier) AS table_name,
           CAST(c.prtype AS character_data) AS privilege_type,
           CAST(
               CASE WHEN
                   -- object owner always has grant options
                   pg_has_role(grantee.oid, c.relowner, 'USAGE')
                   OR c.grantable
                   THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
           CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no)
AS with_hierarchy

    FROM (
        SELECT oid, relname, relnamespace, relkind, relowner,
               (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
        ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee,
               prtype, grantable),
```

```

pg_namespace nc,
pg_authid u_grantor,
(
  SELECT oid, rolname FROM pg_authid
  UNION ALL
  SELECT 0::oid, 'PUBLIC'
) AS grantee (oid, rolname)

WHERE c.relnamespace = nc.oid
  AND c.relkind IN ('r', 'v', 'f')
  AND c.grantee = grantee.oid
  AND c.grantor = u_grantor.oid
  AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE',
'REFERENCES', 'TRIGGER')
  AND (pg_has_role(u_grantor.oid, 'USAGE')
  OR pg_has_role(grantee.oid, 'USAGE')
  OR grantee.rolname = 'PUBLIC');

```

This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)

This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Prevent crash when passing fixed-length pass-by-reference data types to parallel worker processes (Tom Lane)
- Fix crash in `pg_restore` when using parallel mode and using a list file to select a subset of items to restore (Fabrício de Royes Mello)
- Change `ecpg`'s parser to allow RETURNING clauses without attached C variables (Michael Meskes)

This allows `ecpg` programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Change `ecpg`'s parser to recognize backslash continuation of C preprocessor command lines (Michael Meskes)
- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T` is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.

- Fix `make check` to behave correctly when invoked via a non-GNU make program (Thomas Munro)

## E.29. Release 9.6.4

**Release date:** 2017-08-10

This release contains a variety of fixes from 9.6.3. For information about new features in the 9.6 major release, see Section E.33.

## E.29.1. Migration to Version 9.6.4

A dump/restore is not required for those running 9.6.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.6.3, see Section E.30.

## E.29.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you'll still need a restart.)
2. In *each* database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;
CREATE OR REPLACE VIEW pg_user_mappings AS
SELECT
    U.oid        AS umid,
    S.oid        AS srvid,
    S.srvname    AS srvname,
    U.umuser     AS umuser,
    CASE WHEN U.umuser = 0 THEN
        'public'
    ELSE
        A.rolname
    END AS username,
    CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
              AND (pg_has_role(S.srvowner, 'USAGE')
                   OR has_server_privilege(S.oid, 'USAGE')))
        OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
        OR (SELECT rolsuper FROM pg_authid WHERE rolname =
current_user)
    THEN U.umoptions
    ELSE NULL END AS umoptions
FROM pg_user_mapping U
    LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
    pg_foreign_server S ON (U.umserver = S.oid);
```

3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing `template0`, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET dataallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET dataallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

`libpq` ignores empty password specifications, and does not transmit them to the server. So, if a user's password has been set to the empty string, it's impossible to log in with that password via `psql` or other `libpq`-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-`libpq`-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, `md5`, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Make `lo_put()` check for `UPDATE` privilege on the target large object (Tom Lane, Michael Paquier)

`lo_put()` should surely require the same permissions as `lowrite()`, but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)

- Correct the documentation about the process for upgrading standby servers with `pg_upgrade` (Bruce Momjian)

The previous documentation instructed users to start/stop the primary server after running `pg_upgrade` but before syncing the standby servers. This sequence is unsafe.

- Fix concurrent locking of tuple update chains (Álvaro Herrera)

If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose `XMAX` is a multixact with exactly one still-interesting member (Teodor Sigaev)
- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Kopolov)
- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
- Prevent sending SSL session tickets to clients (Tom Lane)

This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting `tcp_keepalives_idle` on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector's receive buffer size is at least 100KB (Tom Lane)

This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an `XLOG_SWITCH` WAL record (Andres Freund)
- Fix walsender to exit promptly when client requests shutdown (Tom Lane)
- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)

This resulted in temporary files consuming excessive disk space.

- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)

The previous algorithm was infeasibly expensive on a server with a lot of open transactions.

- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)
- Reduce overhead in processing syscache invalidation events (Tom Lane)

This is particularly helpful for logical decoding, which triggers frequent cache invalidation.

- Remove incorrect heuristic used in some cases to estimate join selectivity based on the presence of foreign-key constraints (David Rowley)

In some cases where a multi-column foreign key constraint existed but did not exactly match a query's join structure, the planner used an estimation heuristic that turns out not to work well at all. Revert such cases to the way they were estimated before 9.6.

- Fix cases where an `INSERT` or `UPDATE` assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Allow window functions to be used in sub-`SELECT`s that are within the arguments of an aggregate function (Tom Lane)
- Ensure that a view's `CHECK OPTIONS` clause is enforced properly when the underlying table is a foreign table (Etsuro Fujita)

Previously, the update might get pushed entirely to the foreign server, but the need to verify the view conditions was missed if so.

- Move autogenerated array types out of the way during `ALTER ... RENAME` (Vik Fearing)

Previously, we would rename a conflicting autogenerated array type out of the way during `CREATE`; this fix extends that behavior to renaming operations.

- Fix dangling pointer in `ALTER TABLE` when there is a comment on a constraint belonging to the table (David Rowley)

Re-applying the comment to the reconstructed constraint could fail with a weird error message, or even crash.

- Ensure that `ALTER USER ... SET` accepts all the syntax variants that `ALTER ROLE ... SET` does (Peter Eisentraut)
- Allow a foreign table's `CHECK` constraints to be initially `NOT VALID` (Amit Langote)

`CREATE TABLE` silently drops `NOT VALID` specifiers for `CHECK` constraints, reasoning that the table must be empty so the constraint can be validated immediately. But this is wrong for `CREATE FOREIGN TABLE`, where there's no reason to suppose that the underlying table is empty, and even if it is it's no business of ours to decide that the constraint can be treated as valid going forward. Skip this “optimization” for foreign tables.

- Properly update dependency info when changing a datatype I/O function's argument or return type from `opaque` to the correct type (Heikki Linnakangas)

`CREATE TYPE` updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent `DROP TYPE` to leave broken function definitions behind.

- Allow parallelism in the query plan when `COPY` copies from a query's result (Andres Freund)
- Reduce memory usage when `ANALYZE` processes a `tsvector` column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing `money` values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as `regprocedurein()` (Tom Lane)

Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant `#define` symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In `libpq`, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In `psql`, fix failure when `COPY FROM STDIN` is ended with a keyboard EOF signal and then another `COPY FROM STDIN` is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix `pg_dump` and `pg_restore` to emit `REFRESH MATERIALIZED VIEW` commands last (Tom Lane)

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Improve `pg_dump/pg_restore`'s reporting of error conditions originating in `zlib` (Vladimir Kunschikov, Álvaro Herrera)
- Fix `pg_dump` with the `--clean` option to drop event triggers as expected (Tom Lane)

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix `pg_dump` with the `--clean` option to not fail when the `public` schema doesn't exist (Stephen Frost)
- Fix `pg_dump` to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

- Fix `pg_dump` output to stdout on Windows (Kuntal Ghosh)

A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a `NATURAL LEFT JOIN` with no common columns (Tom Lane)
- Fix dumping of function expressions in the `FROM` clause in cases where the expression does not de-parse into something that looks like a function call (Tom Lane)
- Fix `pg_basebackup` output to stdout on Windows (Haribabu Kommi)

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_rewind` to correctly handle files exceeding 2GB (Kuntal Ghosh, Michael Paquier)

Ordinarily such files won't appear in PostgreSQL data directories, but they could be present in some cases.

- Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

- Fix `pg_xlogdump`'s computation of WAL record length (Andres Freund)
- In `postgres_fdw`, re-establish connections to remote servers after `ALTER SERVER` or `ALTER USER MAPPING` commands (Kyotaro Horiguchi)

This ensures that option changes affecting connection parameters will be applied promptly.

- In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)

This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Increase `MAX_SYSCACHE_CALLBACKS` to provide more room for extensions (Tom Lane)
- Always use `-fPIC`, not `-fpic`, when building shared libraries with `gcc` (Tom Lane)

This supports larger extension libraries on platforms where it makes a difference.

- In MSVC builds, handle the case where the `openssl` library is not within a `vc` subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for `libxml2` header files (Andrew Dunstan)

This fixes a former need to move things around in standard Windows installations of `libxml2`.

- In MSVC builds, recognize a Tcl library that is named `tc186.lib` (Noah Misch)
- In MSVC builds, honor `PROVE_FLAGS` settings on `vc regress.pl`'s command line (Andrew Dunstan)

## E.30. Release 9.6.3

**Release date:** 2017-05-11

This release contains a variety of fixes from 9.6.2. For information about new features in the 9.6 major release, see Section E.33.

### E.30.1. Migration to Version 9.6.3

A dump/restore is not required for those running 9.6.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.6.2, see Section E.31.

### E.30.2. Changes

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.29.

- Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator's implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

- Restore libpq's recognition of the `PGREQUIRESSL` environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than `PGSSLMODE`, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

- Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

- Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

- Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Avoid possible crash in `walsender` due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)
- Fix possible crash when rescanning a nearest-neighbor index-only scan on a GiST index (Tom Lane)
- Prevent delays in postmaster's launching of multiple parallel worker processes (Tom Lane)

There could be a significant delay (up to tens of seconds) before satisfying a query's request for more than one worker process, or when multiple queries requested workers simultaneously. On most platforms this required unlucky timing, but on some it was the typical case.

- Fix postmaster's handling of `fork()` failure for a background worker process (Tom Lane)

Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

- Fix possible “no relation entry for relid 0” error when planning nested set operations (Tom Lane)
- Fix assorted minor issues in planning of parallel queries (Robert Haas)
- Avoid applying “physical targetlist” optimization to custom scans (Dmitry Ivanov, Tom Lane)

This optimization supposed that retrieving all columns of a tuple is inexpensive, which is true for ordinary Postgres tuples; but it might not be the case for a custom scan provider.

- Use the correct sub-expression when applying a `FOR ALL` row-level-security policy (Stephen Frost)

In some cases the `WITH CHECK` restriction would be applied when the `USING` restriction is more appropriate.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Avoid dangling pointer in `COPY ... TO` when row-level security is active for the source table (Tom Lane)

Usually this had no ill effects, but sometimes it would cause unexpected errors or crashes.

- Avoid accessing an already-closed `relcache` entry in `CLUSTER` and `VACUUM FULL` (Tom Lane)

With some bad luck, this could lead to indexes on the target relation getting rebuilt with the wrong persistence setting.

- Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
- Fix incorrect support for certain `box` operators in SP-GiST (Nikita Glukhov)

SP-GiST index scans using the operators `&< &>` `&<|` and `|&>` would yield incorrect answers.

- Fix integer-overflow problems in `interval` comparison (Kyotaro Horiguchi, Tom Lane)

The comparison operators for type `interval` could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

- Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

- Fix roundoff problems in `float8_timestampz()` and `make_interval()` (Tom Lane)

These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

- Fix `pg_get_object_address()` to handle members of operator families correctly (Álvaro Herrera)
- Fix cancelling of `pg_stop_backup()` when attempting to stop a non-exclusive backup (Michael Paquier, David Steele)

If `pg_stop_backup()` was cancelled while waiting for a non-exclusive backup to end, related state was left inconsistent; a new exclusive backup could not be started, and there were other minor problems.

- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)
- Reduce memory management overhead for contexts containing many large blocks (Tom Lane)
- Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn't accessible, so that no logging happens at all.

- Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)
- Fix `pgbench` to handle the combination of `--connect` and `--rate` options correctly (Fabien Coelho)
- Fix `pgbench` to honor the long-form option spelling `--builtin`, as per its documentation (Tom Lane)
- Fix `pg_dump/pg_restore` to correctly handle privileges for the `public` schema when using `--clean` option (Stephen Frost)

Other schemas start out with no privileges granted, but `public` does not; this requires special-case treatment when it is dropped and restored due to the `--clean` option.

- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Fix typo in `pg_dump`'s query for initial privileges of a procedural language (Peter Eisentraut)

This resulted in `pg_dump` always believing that the language had no initial privileges. Since that's true for most procedural languages, ill effects from this bug are probably rare.

- Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`'s purposes.

- Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)

Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in `contrib/adminpack`'s `pg_file_write()` function (Noah Misch)

Notably, it failed to detect errors reported by `fclose()`.

- In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix `contrib/pg_trgm`'s extraction of trigrams from regular expressions (Tom Lane)

In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In `contrib/postgres_fdw`, allow join conditions that contain shippable extension-provided functions to be pushed to the remote server (David Rowley, Ashutosh Bapat)
- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release `tzcode2017b` (Tom Lane)

This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to `tzdata` release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the `posixrules` file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates

of the `US/Eastern` zone. If you don't want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

## E.31. Release 9.6.2

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.6.1. For information about new features in the 9.6 major release, see Section E.33.

### E.31.1. Migration to Version 9.6.2

A dump/restore is not required for those running 9.6.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.6.1, see Section E.32.

### E.31.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)

Backends failed to account for this snapshot when advertising their oldest `xmin`, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Fix incorrect WAL logging for BRIN indexes (Kuntal Ghosh)

The WAL record emitted for a BRIN “revmap” page when moving an index tuple to a different page was incorrect. Replay would make the related portion of the index useless, forcing it to be recomputed.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

Previously, this was skipped when `wal_level = minimal`, but actually it's necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)
- Ensure that hot standby feedback works correctly when it's enabled at standby server start (Ants Aasma, Craig Ringer)
- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)
- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Disallow setting the `num_sync` field to zero in `synchronous_standby_names` (Fujii Masao)

The correct way to disable synchronous standby is to set the whole value to an empty string.

- Don't count background worker processes against a user's connection limit (David Rowley)

- Fix check for when an extension member object can be dropped (Tom Lane)

Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Fix tracking of initial privileges for extension member objects so that it works correctly with `ALTER EXTENSION ... ADD/DROP` (Stephen Frost)

An object's current privileges at the time it is added to the extension will now be considered its default privileges; only later changes in its privileges will be dumped by subsequent `pg_dump` runs.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint's deferrability properties with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)

This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

This avoids “could not find trigger *NNN*” or “relation *NNN* has no triggers” errors.

- Fix `ALTER TABLE ... SET DATA TYPE ... USING` when child table has different column ordering than the parent (Álvaro Herrera)

Failure to adjust the column numbering in the `USING` expression led to errors, typically “attribute *N* has wrong type”.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)

The OID column should be treated the same as regular user columns in this case, but it wasn't, leading to odd behavior in later inheritance changes.

- Ensure that `CREATE TABLE ... LIKE ... WITH OIDS` creates a table with OIDs, whether or not the `LIKE`-referenced table(s) have OIDs (Tom Lane)

- Fix `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)

Previously the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)

The wrong catalog OID was reported to extensions such as logical decoding.

- Fix commit timestamp mechanism to not fail when queried about the special XIDs `FrozenTransactionId` and `BootstrapTransactionId` (Craig Ringer)

- Fix incorrect use of view reloptions as regular table reloptions (Tom Lane)

The symptom was spurious “ON CONFLICT is not supported on table ... used as a catalog table” errors when the target of `INSERT ... ON CONFLICT` is a view with cascade option.

- Fix incorrect “target lists can have at most *N* entries” complaint when using `ON CONFLICT` with wide tables (Tom Lane)

- Fix spurious “query provides a value for a dropped column” errors during `INSERT` or `UPDATE` on a table with a dropped column (Tom Lane)

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)

This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)

This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don't share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)

Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Fix execution of `DISTINCT` and ordered aggregates when multiple such aggregates are able to share the same transition state (Heikki Linnakangas)
- Fix implementation of phrase search operators in `tsquery` (Tom Lane)

Remove incorrect, and inconsistently-applied, rewrite rules that tried to transform away `AND/OR/NOT` operators appearing below a `PHRASE` operator; instead upgrade the execution engine to handle such cases correctly. This fixes assorted strange behavior and possible crashes for text search queries containing such combinations. Also fix nested `PHRASE` operators to work sanely in combinations other than simple left-deep trees, correct the behavior when removing stopwords from a phrase search clause, and make sure that index searches behave consistently with simple sequential-scan application of such queries.

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)
- Fix performance problems in `ts_rewrite()` (Tom Lane)
- Fix `ts_rewrite()`'s handling of nested `NOT` operators (Tom Lane)
- Improve speed of user-defined aggregates that use `array_append()` as transition function (Tom Lane)
- Fix `array_fill()` to handle empty arrays properly (Tom Lane)
- Fix possible crash in `array_position()` or `array_positions()` when processing arrays of records (Junseok Yang)
- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)

The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)

This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Disable transform that attempted to remove no-op `AT TIME ZONE` conversions (Tom Lane)

This resulted in wrong answers when the simplified expression was used in an index condition.

- Avoid discarding `interval-to-interval` casts that aren't really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Fix crash if the number of workers available to a parallel query decreases during a rescan (Andreas Seltenreich)
- Fix bugs in transmitting GUC parameter values to parallel workers (Michael Paquier, Tom Lane)
- Allow statements prepared with `PREPARE` to be given parallel plans (Amit Kapila, Tobias Bussmann)
- Fix incorrect generation of parallel plans for semi-joins (Tom Lane)
- Fix planner's cardinality estimates for parallel joins (Robert Haas)

Ensure that these estimates reflect the number of rows predicted to be seen by each worker, rather than the total.

- Fix planner to avoid trying to parallelize plan nodes containing `initplans` or `subplans` (Tom Lane, Amit Kapila)
- Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)
- Fix the plan generated for sorted partial aggregation with a constant `GROUP BY` clause (Tom Lane)
- Fix “could not find plan for CTE” planner error when dealing with a `UNION ALL` containing CTE references (Tom Lane)
- Fix mishandling of `initplans` when forcibly adding a `Material` node to a `subplan` (Tom Lane)

The typical consequence of this mistake was a “plan should not reference subplan's variable” error.

- Fix foreign-key-based join selectivity estimation for semi-joins and anti-joins, as well as inheritance cases (Tom Lane)

The new code for taking the existence of a foreign key relationship into account did the wrong thing in these cases, making the estimates worse not better than the pre-9.6 code.

- Fix `pg_dump` to emit the data of a sequence that is marked as an extension configuration table (Michael Paquier)
- Fix mishandling of `ALTER DEFAULT PRIVILEGES ... REVOKE` in `pg_dump` (Stephen Frost)

`pg_dump` missed issuing the required `REVOKE` commands in cases where `ALTER DEFAULT PRIVILEGES` had been used to reduce privileges to less than they would normally be.

- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix `pg_restore` with `--create --if-exists` to behave more sanely if an archive contains unrecognized `DROP` commands (Tom Lane)

This doesn't fix any live bug, but it may improve the behavior in future if `pg_restore` is used with an archive generated by a later `pg_dump` version.

- Fix `pg_basebackup`'s rate limiting in the presence of slow I/O (Antonin Houska)

If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

- Fix `pg_basebackup`'s handling of symlinked `pg_stat_tmp` and `pg_replslot` subdirectories (Magnus Hagander, Michael Paquier)
- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)
- Improve `initdb` to insert the correct platform-specific default values for the `xxx_flush_after` parameters into `postgresql.conf` (Fabien Coelho, Tom Lane)

This is a cleaner way of documenting the default values than was used previously.

- Fix possible mishandling of expanded arrays in domain check constraints and `CASE` execution (Tom Lane)

It was possible for a PL/pgSQL function invoked in these contexts to modify or even delete an array value that needs to be preserved for additional operations.

- Fix nested uses of PL/pgSQL functions in contexts such as domain check constraints evaluated during assignment to a PL/pgSQL variable (Tom Lane)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)

This matches the (previously undocumented) behavior of PL/Tcl's `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn't a real column named that.

- Allow DOS-style line endings in `~/pgpass` files, even on Unix (Vik Fearing)

This change simplifies use of the same password file across Unix and Windows machines.

- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix incorrect error reporting for duplicate data in `psql's \crosstabview` (Tom Lane)

`psql` sometimes quoted the wrong row and/or column values when complaining about multiple entries for the same crosstab cell.

- Fix `psql's` tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- Fix `psql's` tab completion for `ALTER TABLE t ALTER c DROP ...` (Kyotaro Horiguchi)
- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)

Previously, such a setting caused output intended for the pager to vanish entirely.

- Improve `contrib/dblink's` reporting of low-level `libpq` errors, such as out-of-memory (Joe Conway)
- Teach `contrib/dblink` to ignore irrelevant server options when it uses a `contrib/postgres_fdw` foreign server as the source of connection options (Corey Huinker)

Previously, if the foreign server object had options that were not also `libpq` connection options, an error occurred.

- Fix portability problems in `contrib/pageinspect's` functions for GIN indexes (Peter Eisentraut, Tom Lane)
- Fix possible miss of socket read events while waiting on Windows (Amit Kapila)

This error was harmless for most uses, but it is known to cause hangs when trying to use the `pldebugger` extension.

- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release `tzcode2016j` (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn't support hard links.

- Update time zone data files to `tzdata` release 2016j for DST law changes in northern Cyprus (adding a new zone `Asia/Famagusta`), Russia (adding a new zone `Europe/Saratov`), Tonga, and

Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

## E.32. Release 9.6.1

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.6.0. For information about new features in the 9.6 major release, see Section E.33.

### E.32.1. Migration to Version 9.6.1

A dump/restore is not required for those running 9.6.X.

However, if your installation has been affected by the bugs described in the first two changelog entries below, then after updating you may need to take action to repair corrupted free space maps and/or visibility maps.

### E.32.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block xxx: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at [https://wiki.postgresql.org/wiki/Free\\_Space\\_Map\\_Problems](https://wiki.postgresql.org/wiki/Free_Space_Map_Problems).

- Fix possible data corruption when `pg_upgrade` rewrites a relation visibility map into 9.6 format (Tom Lane)

On big-endian machines, bytes of the new visibility map were written in the wrong order, leading to a completely incorrect map. On Windows, the old map was read using text mode, leading to incorrect results if the map happened to contain consecutive bytes that matched a carriage return/line feed sequence. The latter error would almost always lead to a `pg_upgrade` failure due to the map file appearing to be the wrong length.

If you are using a big-endian machine (many non-Intel architectures are big-endian) and have used `pg_upgrade` to upgrade from a pre-9.6 release, you should assume that all visibility maps are incorrect and need to be regenerated. It is sufficient to truncate each relation's visibility map with `contrib/pg_visibility's pg_truncate_visibility_map()` function. For more information see [https://wiki.postgresql.org/wiki/Visibility\\_Map\\_Problems](https://wiki.postgresql.org/wiki/Visibility_Map_Problems).

- Don't throw serialization errors for self-conflicting insertions in `INSERT ... ON CONFLICT` (Thomas Munro, Peter Geoghegan)
- Fix use-after-free hazard in execution of aggregate functions using `DISTINCT` (Peter Geoghegan)

This could lead to a crash or incorrect query results.

- Fix incorrect handling of polymorphic aggregates used as window functions (Tom Lane)

The aggregate's transition function was told that its first argument and result were of the aggregate's output type, rather than the state type. This led to errors or crashes with polymorphic transition functions.

- Fix `COPY` with a column name list from a table that has row-level security enabled (Adam Brightwell)

- Fix `EXPLAIN` to emit valid XML when `track_io_timing` is on (Markus Winand)

Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- Fix statistics update for `TRUNCATE` in a prepared transaction (Stas Kelvich)
- Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- Show a sensible value in `pg_settings.unit` for `min_wal_size` and `max_wal_size` (Tom Lane)
- Fix replacement of array elements in `jsonb_set()` (Tom Lane)

If the target is an existing JSON array element, it got deleted instead of being replaced with a new value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Preserve commit timestamps across server restart (Julien Rouhaud, Craig Ringer)

With `track_commit_timestamp` turned on, old commit timestamps became inaccessible after a clean server restart.

- Fix logical WAL decoding to work properly when a subtransaction's WAL output is large enough to spill to disk (Andres Freund)
- Fix dangling-pointer problem in logical WAL decoding (Stas Kelvich)
- Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)

This avoids possible failures during `munmap()` on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.

- Don't try to share SSL contexts across multiple connections in `libpq` (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in `libpq` (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

- In `pg_upgrade`, check library loadability in name order (Tom Lane)

This is a workaround to deal with cross-extension dependencies from language transform modules to their base language and data type modules.

- Fix `pg_upgrade` to work correctly for extensions containing index access methods (Tom Lane)

To allow this, the server has been extended to support `ALTER EXTENSION ADD/DROP ACCESS METHOD`. That functionality should have been included in the original patch to support dynamic creation of access methods, but it was overlooked.

- Improve error reporting in `pg_upgrade`'s file copying/linking/rewriting steps (Tom Lane, Álvaro Herrera)
- Fix `pg_dump` to work against pre-7.4 servers (Amit Langote, Tom Lane)
- Disallow specifying both `--source-server` and `--source-target` options to `pg_rewind` (Michael Banck)

- Make `pg_rewind` turn off `synchronous_commit` in its session on the source server (Michael Banck, Michael Paquier)

This allows `pg_rewind` to work even when the source server is using synchronous replication that is not working for some reason.

- In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Hagan-der)

This allows for a possible delay in the server's creation of the next segment.

- Fix `contrib/pg_visibility` to report the correct TID for a corrupt tuple that has been the subject of a rolled-back update (Tom Lane)
- Fix makefile dependencies so that parallel make of PL/Python by itself will succeed reliably (Pavel Raiskup)
- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, `AMT` is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the `Default` abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

## E.33. Release 9.6

**Release date:** 2016-09-29

### E.33.1. Overview

Major enhancements in PostgreSQL 9.6 include:

- Parallel execution of sequential scans, joins and aggregates
- Avoid scanning pages unnecessarily during vacuum freeze operations
- Synchronous replication now allows multiple standby servers for increased reliability
- Full-text search can now search for phrases (multiple adjacent words)
- `postgres_fdw` now supports remote joins, sorts, `UPDATES`, and `DELETES`
- Substantial performance improvements, especially in the area of scalability on multi-CPU-socket servers

The above items are explained in more detail in the sections below.

### E.33.2. Migration to Version 9.6

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.6 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Improve the `pg_stat_activity` view's information about what a process is waiting for (Amit Kapila, Ildus Kurbangaliev)

Historically a process has only been shown as waiting if it was waiting for a heavyweight lock. Now waits for lightweight locks and buffer pins are also shown in `pg_stat_activity`. Also, the type of

lock being waited for is now visible. These changes replace the `waiting` column with `wait_event_type` and `wait_event`.

- In `to_char()`, do not count a minus sign (when needed) as part of the field width for time-related fields (Bruce Momjian)

For example, `to_char('-4 years'::interval, 'YY')` now returns `-04`, rather than `-4`.

- Make `extract()` behave more reasonably with infinite inputs (Vitaly Burovoy)

Historically the `extract()` function just returned zero given an infinite timestamp, regardless of the given field name. Make it return `infinity` or `-infinity` as appropriate when the requested field is one that is monotonically increasing (e.g. `year`, `epoch`), or `NULL` when it is not (e.g., `day`, `hour`). Also, throw the expected error for bad field names.

- Remove PL/pgSQL's "feature" that suppressed the innermost line of `CONTEXT` for messages emitted by `RAISE` commands (Pavel Stehule)

This ancient backwards-compatibility hack was agreed to have outlived its usefulness.

- Fix the default text search parser to allow leading digits in `email` and `host` tokens (Artur Zakirov)

In most cases this will result in few changes in the parsing of text. But if you have data where such addresses occur frequently, it may be worth rebuilding dependent `tsvector` columns and indexes so that addresses of this form will be found properly by text searches.

- Extend `contrib/unaccent`'s standard `unaccent.rules` file to handle all diacritics known to Unicode, and to expand ligatures correctly (Thomas Munro, Léonard Benedetti)

The previous version neglected to convert some less-common letters with diacritic marks. Also, ligatures are now expanded into separate letters. Installations that use this rules file may wish to rebuild `tsvector` columns and indexes that depend on the result.

- Remove the long-deprecated `CREATEUSER/NOCREATEUSER` options from `CREATE ROLE` and allied commands (Tom Lane)

`CREATEUSER` actually meant `SUPERUSER`, for ancient backwards-compatibility reasons. This has been a constant source of confusion for people who (reasonably) expect it to mean `CREATEROLE`. It has been deprecated for ten years now, so fix the problem by removing it.

- Treat role names beginning with `pg_` as reserved (Stephen Frost)

User creation of such role names is now disallowed. This prevents conflicts with built-in roles created by `initdb`.

- Change a column name in the `information_schema.routines` view from `result_cast_character_set_name` to `result_cast_char_set_name` (Clément Prévost)

The SQL:2011 standard specifies the longer name, but that appears to be a mistake, because adjacent column names use the shorter style, as do other `information_schema` views.

- `psql`'s `-c` option no longer implies `--no-psqlrc` (Pavel Stehule, Catalin Iacob)

Write `--no-psqlrc` (or its abbreviation `-X`) explicitly to obtain the old behavior. Scripts so modified will still work with old versions of `psql`.

- Improve `pg_restore`'s `-t` option to match all types of relations, not only plain tables (Craig Ringer)
- Change the display format used for `NextXID` in `pg_controldata` and related places (Joe Conway, Bruce Momjian)

Display epoch-and-transaction-ID values in the format `number:number`. The previous format `number/number` was confusingly similar to that used for LSNs.

- Update extension functions to be marked parallel-safe where appropriate (Andreas Karlsson)

Many of the standard extensions have been updated to allow their functions to be executed within parallel query worker processes. These changes will not take effect in databases `pg_upgrade'd` from prior versions unless you apply `ALTER EXTENSION UPDATE` to each such extension (in each database of a cluster).

### E.33.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.6 and the previous major release.

#### E.33.3.1. Server

##### E.33.3.1.1. Parallel Queries

- Parallel queries (Robert Haas, Amit Kapila, David Rowley, many others)

With 9.6, PostgreSQL introduces initial support for parallel execution of large queries. Only strictly read-only queries where the driving table is accessed via a sequential scan can be parallelized. Hash joins and nested loops can be performed in parallel, as can aggregation (for supported aggregates). Much remains to be done, but this is already a useful set of features.

Parallel query execution is not (yet) enabled by default. To allow it, set the new configuration parameter `max_parallel_workers_per_gather` to a value larger than zero. Additional control over use of parallelism is available through other new configuration parameters `force_parallel_mode`, `parallel_setup_cost`, `parallel_tuple_cost`, and `min_parallel_relation_size`.

- Provide infrastructure for marking the parallel-safety status of functions (Robert Haas, Amit Kapila)

##### E.33.3.1.2. Indexes

- Allow GIN index builds to make effective use of `maintenance_work_mem` settings larger than 1 GB (Robert Abraham, Teodor Sigaev)
- Add pages deleted from a GIN index's pending list to the free space map immediately (Jeff Janes, Teodor Sigaev)

This reduces bloat if the table is not vacuumed often.

- Add `gin_clean_pending_list()` function to allow manual invocation of pending-list cleanup for a GIN index (Jeff Janes)

Formerly, such cleanup happened only as a byproduct of vacuuming or analyzing the parent table.

- Improve handling of dead index tuples in GiST indexes (Anastasia Lubennikova)

Dead index tuples are now marked as such when an index scan notices that the corresponding heap tuple is dead. When inserting tuples, marked-dead tuples will be removed if needed to make space on the page.

- Add an SP-GiST operator class for type `box` (Alexander Lebedev)

##### E.33.3.1.3. Sorting

- Improve sorting performance by using quicksort, not replacement selection sort, when performing external sort steps (Peter Geoghegan)

The new approach makes better use of the CPU cache for typical cache sizes and data volumes. Where necessary, the behavior can be adjusted via the new configuration parameter `replacement_sort_tuples`.

- Speed up text sorts where the same string occurs multiple times (Peter Geoghegan)
- Speed up sorting of `uuid`, `bytea`, and `char(n)` fields by using “abbreviated” keys (Peter Geoghegan)

Support for abbreviated keys has also been added to the non-default operator classes `text_pattern_ops`, `varchar_pattern_ops`, and `bpchar_pattern_ops`. Processing of ordered-set aggregates can also now exploit abbreviated keys.

- Speed up `CREATE INDEX CONCURRENTLY` by treating TIDs as 64-bit integers during sorting (Peter Geoghegan)

#### **E.33.3.1.4. Locking**

- Reduce contention for the `ProcArrayLock` (Amit Kapila, Robert Haas)
- Improve performance by moving buffer content locks into the buffer descriptors (Andres Freund, Simon Riggs)
- Replace shared-buffer header spinlocks with atomic operations to improve scalability (Alexander Korotkov, Andres Freund)
- Use atomic operations, rather than a spinlock, to protect an `LWLock`'s wait queue (Andres Freund)
- Partition the shared hash table freelist to reduce contention on multi-CPU-socket servers (Aleksander Alekseev)
- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

This change avoids substantial replication delays that sometimes occurred while replaying such operations.

#### **E.33.3.1.5. Optimizer Statistics**

- Improve `ANALYZE`'s estimates for columns with many nulls (Tomas Vondra, Alex Shulgin)

Previously `ANALYZE` tended to underestimate the number of non-NULL distinct values in a column with many NULLS, and was also inaccurate in computing the most-common values.

- Improve planner's estimate of the number of distinct values in a query result (Tomas Vondra)
- Use foreign key relationships to infer selectivity for join predicates (Tomas Vondra, David Rowley)

If a table `t` has a foreign key restriction, say `(a,b) REFERENCES r (x,y)`, then a `WHERE` condition such as `t.a = r.x AND t.b = r.y` cannot select more than one `r` row per `t` row. The planner formerly considered these `AND` conditions to be independent and would often drastically misestimate selectivity as a result. Now it compares the `WHERE` conditions to applicable foreign key constraints and produces better estimates.

#### **E.33.3.1.6. VACUUM**

- Avoid re-vacuuming pages containing only frozen tuples (Masahiko Sawada, Robert Haas, Andres Freund)

Formerly, anti-wraparound vacuum had to visit every page of a table, even pages where there was nothing to do. Now, pages containing only already-frozen tuples are identified in the table's visibility map, and can be skipped by vacuum even when doing transaction wraparound prevention. This should greatly reduce the cost of maintaining large tables containing mostly-unchanging data.

If necessary, vacuum can be forced to process all-frozen pages using the new `DISABLE_PAGE_SKIPPING` option. Normally this should never be needed, but it might help in recovering from visibility-map corruption.

- Avoid useless heap-truncation attempts during `VACUUM` (Jeff Janes, Tom Lane)

This change avoids taking an exclusive table lock in some cases where no truncation is possible. The main benefit comes from avoiding unnecessary query cancellations on standby servers.

#### **E.33.3.1.7. General Performance**

- Allow old MVCC snapshots to be invalidated after a configurable timeout (Kevin Grittner)

Normally, deleted tuples cannot be physically removed by vacuuming until the last transaction that could “see” them is gone. A transaction that stays open for a long time can thus cause considerable table bloat because space cannot be recycled. This feature allows setting a time-based limit, via the new configuration parameter `old_snapshot_threshold`, on how long an MVCC snapshot is guaranteed to be valid. After that, dead tuples are candidates for removal. A transaction using an outdated snapshot will get an error if it attempts to read a page that potentially could have contained such data.

- Ignore `GROUP BY` columns that are functionally dependent on other columns (David Rowley)

If a `GROUP BY` clause includes all columns of a non-deferred primary key, as well as other columns of the same table, those other columns are redundant and can be dropped from the grouping. This saves computation in many common cases.

- Allow use of an index-only scan on a partial index when the index's `WHERE` clause references columns that are not indexed (Tomas Vondra, Kyotaro Horiguchi)

For example, an index defined by `CREATE INDEX tidx_partial ON t(b) WHERE a > 0` can now be used for an index-only scan by a query that specifies `WHERE a > 0` and does not otherwise use `a`. Previously this was disallowed because `a` is not listed as an index column.

- Perform checkpoint writes in sorted order (Fabien Coelho, Andres Freund)

Previously, checkpoints wrote out dirty pages in whatever order they happen to appear in shared buffers, which usually is nearly random. That performs poorly, especially on rotating media. This change causes checkpoint-driven writes to be done in order by file and block number, and to be balanced across tablespaces.

- Where feasible, trigger kernel writeback after a configurable number of writes, to prevent accumulation of dirty data in kernel disk buffers (Fabien Coelho, Andres Freund)

PostgreSQL writes data to the kernel's disk cache, from where it will be flushed to physical storage in due time. Many operating systems are not smart about managing this and allow large amounts of dirty data to accumulate before deciding to flush it all at once, causing long delays for new I/O requests until the flushing finishes. This change attempts to alleviate this problem by explicitly requesting data flushes after a configurable interval.

On Linux, `sync_file_range()` is used for this purpose, and the feature is on by default on Linux because that function has few downsides. This flushing capability is also available on other platforms if they have `msync()` or `posix_fadvise()`, but those interfaces have some undesirable side-effects so the feature is disabled by default on non-Linux platforms.

The new configuration parameters `backend_flush_after`, `bgwriter_flush_after`, `checkpoint_flush_after`, and `wal_writer_flush_after` control this behavior.

- Improve aggregate-function performance by sharing calculations across multiple aggregates if they have the same arguments and transition functions (David Rowley)

For example, `SELECT AVG(x), VARIANCE(x) FROM tab` can use a single per-row computation for both aggregates.

- Speed up visibility tests for recently-created tuples by checking the current transaction's snapshot, not `pg_clog`, to decide if the source transaction should be considered committed (Jeff Janes, Tom Lane)
- Allow tuple hint bits to be set sooner than before (Andres Freund)
- Improve performance of short-lived prepared transactions (Stas Kelvich, Simon Riggs, Pavan Deolasee)

Two-phase commit information is now written only to WAL during `PREPARE TRANSACTION`, and will be read back from WAL during `COMMIT PREPARED` if that happens soon thereafter. A separate state

file is created only if the pending transaction does not get committed or aborted by the time of the next checkpoint.

- Improve performance of memory context destruction (Jan Wieck)
- Improve performance of resource owners with many tracked objects (Aleksander Alekseev)
- Improve speed of the output functions for `timestamp`, `time`, and `date` data types (David Rowley, Andres Freund)
- Avoid some unnecessary cancellations of hot-standby queries during replay of actions that take `AccessExclusive` locks (Jeff Janes)
- Extend relations multiple blocks at a time when there is contention for the relation's extension lock (Dilip Kumar)

This improves scalability by decreasing contention.

- Increase the number of clog buffers for better scalability (Amit Kapila, Andres Freund)
- Speed up expression evaluation in PL/pgSQL by keeping `ParamListInfo` entries for simple variables valid at all times (Tom Lane)
- Avoid reducing the `SO_SNDBUF` setting below its default on recent Windows versions (Chen Huajun)
- Disable `update_process_title` by default on Windows (Takayuki Tsunakawa)

The overhead of updating the process title is much larger on Windows than most other platforms, and it is also less useful to do it since most Windows users do not have tools that can display process titles.

#### **E.33.3.1.8. Monitoring**

- Add `pg_stat_progress_vacuum` system view to provide progress reporting for `VACUUM` operations (Amit Langote, Robert Haas, Vinayak Pokale, Rahila Syed)
- Add `pg_control_system()`, `pg_control_checkpoint()`, `pg_control_recovery()`, and `pg_control_init()` functions to expose fields of `pg_control` to SQL (Joe Conway, Michael Paquier)
- Add `pg_config` system view (Joe Conway)

This view exposes the same information available from the `pg_config` command-line utility, namely assorted compile-time configuration information for PostgreSQL.

- Add a `confirmed_flush_lsn` column to the `pg_replication_slots` system view (Marko Tiikkaja)
- Add `pg_stat_wal_receiver` system view to provide information about the state of a hot-standby server's WAL receiver process (Michael Paquier)
- Add `pg_blocking_pids()` function to reliably identify which sessions block which others (Tom Lane)

This function returns an array of the process IDs of any sessions that are blocking the session with the given process ID. Historically users have obtained such information using a self-join on the `pg_locks` view. However, it is unreasonably tedious to do it that way with any modicum of correctness, and the addition of parallel queries has made the old approach entirely impractical, since locks might be held or awaited by child worker processes rather than the session's main process.

- Add function `pg_current_xlog_flush_location()` to expose the current transaction log flush location (Tomas Vondra)
- Add function `pg_notification_queue_usage()` to report how full the `NOTIFY` queue is (Brendan Juurd)
- Limit the verbosity of memory context statistics dumps (Tom Lane)

The memory usage dump that is output to the postmaster log during an out-of-memory failure now summarizes statistics when there are a large number of memory contexts, rather than possibly generating a very large report. There is also a “grand total” summary line now.

### E.33.3.1.9. Authentication

- Add a BSD authentication method to allow use of the BSD Authentication service for PostgreSQL client authentication (Marisa Emerson)

BSD Authentication is currently only available on OpenBSD.

- When using PAM authentication, provide the client IP address or host name to PAM modules via the `PAM_RHOST` item (Grzegorz Sampolski)
- Provide detail in the postmaster log for more types of password authentication failure (Tom Lane)

All ordinarily-reachable password authentication failure cases should now provide specific `DETAIL` fields in the log.

- Support RADIUS passwords up to 128 characters long (Marko Tiikkaja)
- Add new SSPI authentication parameters `compat_realm` and `upn_username` to control whether Net-BIOS or Kerberos realm names and user names are used during SSPI authentication (Christian Ullrich)

### E.33.3.1.10. Server Configuration

- Allow sessions to be terminated automatically if they are in idle-in-transaction state for too long (Vik Fearing)

This behavior is controlled by the new configuration parameter `idle_in_transaction_session_timeout`. It can be useful to prevent forgotten transactions from holding locks or preventing vacuum cleanup for too long.

- Raise the maximum allowed value of `checkpoint_timeout` to 24 hours (Simon Riggs)
- Allow `effective_io_concurrency` to be set per-tablespace to support cases where different tablespaces have different I/O characteristics (Julien Rouhaud)
- Add `log_line_prefix` option `%n` to print the current time in Unix epoch form, with milliseconds (Tomas Vondra, Jeff Davis)
- Add `syslog_sequence_numbers` and `syslog_split_messages` configuration parameters to provide more control over the message format when logging to syslog (Peter Eisentraut)
- Merge the `archive` and `hot_standby` values of the `wal_level` configuration parameter into a single new value `replica` (Peter Eisentraut)

Making a distinction between these settings is no longer useful, and merging them is a step towards a planned future simplification of replication setup. The old names are still accepted but are converted to `replica` internally.

- Add configure option `--with-systemd` to enable calling `sd_notify()` at server start and stop (Peter Eisentraut)

This allows the use of systemd service units of type `notify`, which greatly simplifies the management of PostgreSQL under systemd.

- Allow the server's SSL key file to have group read access if it is owned by `root` (Christoph Berg)

Formerly, we insisted the key file be owned by the user running the PostgreSQL server, but that is inconvenient on some systems (such as Debian) that are configured to manage certificates centrally. Therefore, allow the case where the key file is owned by `root` and has group read access. It is up to the operating system administrator to ensure that the group does not include any untrusted users.

### E.33.3.1.11. Reliability

- Force backends to exit if the postmaster dies (Rajeev Rastogi, Robert Haas)

Under normal circumstances the postmaster should always outlive its child processes. If for some reason the postmaster dies, force backend sessions to exit with an error. Formerly, existing back-

ends would continue to run until their clients disconnect, but that is unsafe and inefficient. It also prevents a new postmaster from being started until the last old backend has exited. Backends will detect postmaster death when waiting for client I/O, so the exit will not be instantaneous, but it should happen no later than the end of the current query.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Ensure that invalidation messages are recorded in WAL even when issued by a transaction that has no XID assigned (Andres Freund)

This fixes some corner cases in which transactions on standby servers failed to notice changes, such as new indexes.

- Prevent multiple processes from trying to clean a GIN index's pending list concurrently (Teodor Sigaev, Jeff Janes)

This had been intentionally allowed, but it causes race conditions that can result in vacuum missing index entries it needs to delete.

### E.33.3.2. Replication and Recovery

- Allow synchronous replication to support multiple simultaneous synchronous standby servers, not just one (Masahiko Sawada, Beena Emerson, Michael Paquier, Fujii Masao, Kyotaro Horiguchi)

The number of standby servers that must acknowledge a commit before it is considered complete is now configurable as part of the `synchronous_standby_names` parameter.

- Add new setting `remote_apply` for configuration parameter `synchronous_commit` (Thomas Munro)

In this mode, the master waits for the transaction to be *applied* on the standby server, not just written to disk. That means that you can count on a transaction started on the standby to see all commits previously acknowledged by the master.

- Add a feature to the replication protocol, and a corresponding option to `pg_create_physical_replication_slot()`, to allow reserving WAL immediately when creating a replication slot (Gurjeet Singh, Michael Paquier)

This allows the creation of a replication slot to guarantee that all the WAL needed for a base backup will be available.

- Add a `--slot` option to `pg_basebackup` (Peter Eisentraut)

This lets `pg_basebackup` use a replication slot defined for WAL streaming. After the base backup completes, selecting the same slot for regular streaming replication allows seamless startup of the new standby server.

- Extend `pg_start_backup()` and `pg_stop_backup()` to support non-exclusive backups (Magnus Hagander)

### E.33.3.3. Queries

- Allow functions that return sets of tuples to return simple NULLS (Andrew Gierth, Tom Lane)

In the context of `SELECT FROM function(...)`, a function that returned a set of composite values was previously not allowed to return a plain NULL value as part of the set. Now that is allowed and interpreted as a row of NULLS. This avoids corner-case errors with, for example, unnesting an array of composite values.

- Fully support array subscripts and field selections in the target column list of an `INSERT` with multiple `VALUES` rows (Tom Lane)

Previously, such cases failed if the same target column was mentioned more than once, e.g., `INSERT INTO tab (x[1], x[2]) VALUES (...)`.

- When appropriate, postpone evaluation of `SELECT` output expressions until after an `ORDER BY` sort (Konstantin Knizhnik)

This change ensures that volatile or expensive functions in the output list are executed in the order suggested by `ORDER BY`, and that they are not evaluated more times than required when there is a `LIMIT` clause. Previously, these properties held if the ordering was performed by an index scan or pre-merge-join sort, but not if it was performed by a top-level sort.

- Widen counters recording the number of tuples processed to 64 bits (Andreas Scherbaum)

This change allows command tags, e.g. `SELECT`, to correctly report tuple counts larger than 4 billion. This also applies to PL/pgSQL's `GET DIAGNOSTICS ... ROW_COUNT` command.

- Avoid doing encoding conversions by converting through the `MULE_INTERNAL` encoding (Tom Lane)

Previously, many conversions for Cyrillic and Central European single-byte encodings were done by converting to a related `MULE_INTERNAL` coding scheme and then to the destination encoding. Aside from being inefficient, this meant that when the conversion encountered an untranslatable character, the error message would confusingly complain about failure to convert to or from `MULE_INTERNAL`, rather than the user-visible encoding.

- Consider performing joins of foreign tables remotely only when the tables will be accessed under the same role ID (Shigeru Hanada, Ashutosh Bapat, Etsuro Fujita)

Previously, the foreign join pushdown infrastructure left the question of security entirely up to individual foreign data wrappers, but that made it too easy for an FDW to inadvertently create subtle security holes. So, make it the core code's job to determine which role ID will access each table, and do not attempt join pushdown unless the role is the same for all relevant relations.

### E.33.3.4. Utility Commands

- Allow `COPY` to copy the output of an `INSERT/UPDATE/DELETE ... RETURNING` query (Marko Tiikkaja)

Previously, an intermediate CTE had to be written to get this result.

- Introduce `ALTER object DEPENDS ON EXTENSION` (Abhijit Menon-Sen)

This command allows a database object to be marked as depending on an extension, so that it will be dropped automatically if the extension is dropped (without needing `CASCADE`). However, the object is not part of the extension, and thus will be dumped separately by `pg_dump`.

- Make `ALTER object SET SCHEMA` do nothing when the object is already in the requested schema, rather than throwing an error as it historically has for most object types (Marti Raudsepp)
- Add options to `ALTER OPERATOR` to allow changing the selectivity functions associated with an existing operator (Yury Zhuravlev)
- Add an `IF NOT EXISTS` option to `ALTER TABLE ADD COLUMN` (Fabrízio de Royes Mello)
- Reduce the lock strength needed by `ALTER TABLE` when setting fillfactor and autovacuum-related relation options (Fabrízio de Royes Mello, Simon Riggs)
- Introduce `CREATE ACCESS METHOD` to allow extensions to create index access methods (Alexander Korotkov, Petr Jelínek)
- Add a `CASCADE` option to `CREATE EXTENSION` to automatically create any extensions the requested one depends on (Petr Jelínek)
- Make `CREATE TABLE ... LIKE` include an `OID` column if any source table has one (Bruce Momjian)

- If a `CHECK` constraint is declared `NOT VALID` in a table creation command, automatically mark it as valid (Amit Langote, Amul Sul)

This is safe because the table has no existing rows. This matches the longstanding behavior of `FOREIGN KEY` constraints.

- Fix `DROP OPERATOR` to clear `pg_operator.oprcom` and `pg_operator.oprnegate` links to the dropped operator (Roma Sokolov)

Formerly such links were left as-is, which could pose a problem in the somewhat unlikely event that the dropped operator's `OID` was reused for another operator.

- Do not show the same subplan twice in `EXPLAIN` output (Tom Lane)

In certain cases, typically involving `SubPlan` nodes in index conditions, `EXPLAIN` would print data for the same subplan twice.

- Disallow creation of indexes on system columns, except for `OID` columns (David Rowley)

Such indexes were never considered supported, and would very possibly misbehave since the system might change the system-column fields of a tuple without updating indexes. However, previously there were no error checks to prevent them from being created.

### E.33.3.5. Permissions Management

- Use the privilege system to manage access to sensitive functions (Stephen Frost)

Formerly, many security-sensitive functions contained hard-wired checks that would throw an error if they were called by a non-superuser. This forced the use of superuser roles for some relatively pedestrian tasks. The hard-wired error checks are now gone in favor of making `initdb` revoke the default public `EXECUTE` privilege on these functions. This allows installations to choose to grant usage of such functions to trusted roles that do not need all superuser privileges.

- Create some built-in roles that can be used to grant access to what were previously superuser-only functions (Stephen Frost)

Currently the only such role is `pg_signal_backend`, but more are expected to be added in future.

### E.33.3.6. Data Types

- Improve full-text search to support searching for phrases, that is, lexemes appearing adjacent to each other in a specific order, or with a specified distance between them (Teodor Sigaev, Oleg Bartunov, Dmitry Ivanov)

A phrase-search query can be specified in `tsquery` input using the new operators `<->` and `<N>`. The former means that the lexemes before and after it must appear adjacent to each other in that order. The latter means they must be exactly `N` lexemes apart.

- Allow omitting one or both boundaries in an array slice specifier, e.g. `array_col[3:]` (Yury Zhuravlev)

Omitted boundaries are taken as the upper or lower limit of the corresponding array subscript. This allows simpler specification for many common use-cases.

- Be more careful about out-of-range dates and timestamps (Vitaly Burovoy)

This change prevents unexpected out-of-range errors for `timestamp with time zone` values very close to the implementation limits. Previously, the “same” value might be accepted or not depending on the `timezone` setting, meaning that a dump and reload could fail on a value that had been accepted when presented. Now the limits are enforced according to the equivalent UTC time, not local time, so as to be independent of `timezone`.

Also, PostgreSQL is now more careful to detect overflow in operations that compute new date or timestamp values, such as `date + integer`.

- For geometric data types, make sure `infinity` and `NaN` component values are treated consistently during input and output (Tom Lane)

Such values will now always print the same as they would in a simple `float8` column, and be accepted the same way on input. Previously the behavior was platform-dependent.

- Upgrade the `ispell` dictionary type to handle modern Hunspell files and support more languages (Artur Zakirov)
- Implement look-behind constraints in regular expressions (Tom Lane)

A look-behind constraint is like a lookahead constraint in that it consumes no text; but it checks for existence (or nonexistence) of a match ending at the current point in the string, rather than one starting at the current point. Similar features exist in many other regular-expression engines.

- In regular expressions, if an apparent three-digit octal escape `\nnn` would exceed 377 (255 decimal), assume it is a two-digit octal escape instead (Tom Lane)

This makes the behavior match current Tcl releases.

- Add transaction ID operators `xid <> xid` and `xid <> int4`, for consistency with the corresponding equality operators (Michael Paquier)

### E.33.3.7. Functions

- Add `jsonb_insert()` function to insert a new element into a `jsonb` array, or a not-previously-existing key into a `jsonb` object (Dmitry Dolgov)
- Improve the accuracy of the `ln()`, `log()`, `exp()`, and `pow()` functions for type `numeric` (Dean Rasheed)
- Add a `scale(numeric)` function to extract the display scale of a `numeric` value (Marko Tiikkaja)
- Add trigonometric functions that work in degrees (Dean Rasheed)

For example, `sind()` measures its argument in degrees, whereas `sin()` measures in radians. These functions go to some lengths to deliver exact results for values where an exact result can be expected, for instance `sind(30) = 0.5`.

- Ensure that trigonometric functions handle `infinity` and `NaN` inputs per the POSIX standard (Dean Rasheed)

The POSIX standard says that these functions should return `NaN` for `NaN` input, and should throw an error for out-of-range inputs including `infinity`. Previously our behavior varied across platforms.

- Make `to_timestamp(float8)` convert float `infinity` to timestamp `infinity` (Vitaly Burovoy)

Formerly it just failed on an infinite input.

- Add new functions for `tsvector` data (Stas Kelvich)

The new functions are `ts_delete()`, `ts_filter()`, `unnest()`, `tsvector_to_array()`, `array_to_tsvector()`, and a variant of `setweight()` that sets the weight only for specified lexeme(s).

- Allow `ts_stat()` and `tsvector_update_trigger()` to operate on values that are of types binary-compatible with the expected argument type, not just exactly that type; for example allow `ci-text` where `text` is expected (Teodor Sigaev)
- Add variadic functions `num_nulls()` and `num_nonnulls()` that count the number of their arguments that are null or non-null (Marko Tiikkaja)

An example usage is `CHECK(num_nonnulls(a,b,c) = 1)` which asserts that exactly one of `a,b,c` is not `NULL`. These functions can also be used to count the number of null or nonnull elements in an array.

- Add function `parse_ident()` to split a qualified, possibly quoted SQL identifier into its parts (Pavel Stehule)
- In `to_number()`, interpret a `v` format code as dividing by 10 to the power of the number of digits following `v` (Bruce Momjian)

This makes it operate in an inverse fashion to `to_char()`.

- Make the `to_reg*()` functions accept type `text not cstring` (Petr Korobeinikov)

This avoids the need to write an explicit cast in most cases where the argument is not a simple literal constant.

- Add `pg_size_bytes()` function to convert human-readable size strings to numbers (Pavel Stehule, Vitaly Burovoy, Dean Rasheed)

This function converts strings like those produced by `pg_size_pretty()` into bytes. An example usage is `SELECT oid::regclass FROM pg_class WHERE pg_total_relation_size(oid) > pg_size_bytes('10 GB')`.

- In `pg_size_pretty()`, format negative numbers similarly to positive ones (Adrian Vondendriesch)

Previously, negative numbers were never abbreviated, just printed in bytes.

- Add an optional `missing_ok` argument to the `current_setting()` function (David Christensen)

This allows avoiding an error for an unrecognized parameter name, instead returning a `NULL`.

- Change various catalog-inspection functions to return `NULL` for invalid input (Michael Paquier)

`pg_get_viewdef()` now returns `NULL` if given an invalid view `OID`, and several similar functions likewise return `NULL` for bad input. Previously, such cases usually led to “cache lookup failed” errors, which are not meant to occur in user-facing cases.

- Fix `pg_replication_origin_xact_reset()` to not have any arguments (Fujii Masao)

The documentation said that it has no arguments, and the C code did not expect any arguments, but the entry in `pg_proc` mistakenly specified two arguments.

### E.33.3.8. Server-Side Languages

- In PL/pgSQL, detect mismatched `CONTINUE` and `EXIT` statements while compiling a function, rather than at execution time (Jim Nasby)
- Extend PL/Python's error-reporting and message-reporting functions to allow specifying additional message fields besides the primary error message (Pavel Stehule)
- Allow PL/Python functions to call themselves recursively via SPI, and fix the behavior when multiple set-returning PL/Python functions are called within one query (Alexey Grishchenko, Tom Lane)
- Fix session-lifespan memory leaks in PL/Python (Heikki Linnakangas, Haribabu Kommi, Tom Lane)
- Modernize PL/Tcl to use Tcl's “object” APIs instead of simple strings (Jim Nasby, Karl Lehenbauer)

This can improve performance substantially in some cases. Note that PL/Tcl now requires Tcl 8.4 or later.

- In PL/Tcl, make database-reported errors return additional information in Tcl's `errorCode` global variable (Jim Nasby, Tom Lane)

This feature follows the Tcl convention for returning auxiliary data about an error.

- Fix PL/Tcl to perform encoding conversion between the database encoding and UTF-8, which is what Tcl expects (Tom Lane)

Previously, strings were passed through without conversion, leading to misbehavior with non-ASCII characters when the database encoding was not UTF-8.

### E.33.3.9. Client Interfaces

- Add a nonlocalized version of the severity field in error and notice messages (Tom Lane)

This change allows client code to determine severity of an error or notice without having to worry about localized variants of the severity strings.

- Introduce a feature in libpq whereby the `CONTEXT` field of messages can be suppressed, either always or only for non-error messages (Pavel Stehule)

The default behavior of `PQerrorMessage()` is now to print `CONTEXT` only for errors. The new function `PQsetErrorContextVisibility()` can be used to adjust this.

- Add support in libpq for regenerating an error message with a different verbosity level (Alex Shulgin)

This is done with the new function `PQresultVerboseErrorMessage()`. This supports `psql`'s new `\errverbose` feature, and may be useful for other clients as well.

- Improve libpq's `PQhost()` function to return useful data for default Unix-socket connections (Tom Lane)

Previously it would return `NULL` if no explicit host specification had been given; now it returns the default socket directory path.

- Fix `ecpg`'s lexer to handle line breaks within comments starting on preprocessor directive lines (Michael Meskes)

### E.33.3.10. Client Applications

- Add a `--strict-names` option to `pg_dump` and `pg_restore` (Pavel Stehule)

This option causes the program to complain if there is no match for a `-t` or `-n` option, rather than silently doing nothing.

- In `pg_dump`, dump locally-made changes of privilege assignments for system objects (Stephen Frost)

While it has always been possible for a superuser to change the privilege assignments for built-in or extension-created objects, such changes were formerly lost in a dump and reload. Now, `pg_dump` recognizes and dumps such changes. (This works only when dumping from a 9.6 or later server, however.)

- Allow `pg_dump` to dump non-extension-owned objects that are within an extension-owned schema (Martín Marqués)

Previously such objects were ignored because they were mistakenly assumed to belong to the extension owning their schema.

- In `pg_dump` output, include the table name in object tags for object types that are only uniquely named per-table (for example, triggers) (Peter Eisentraut)

- Support multiple `-c` and `-f` command-line options (Pavel Stehule, Catalin Iacob)

The specified operations are carried out in the order in which the options are given, and then `psql` terminates.

- Add a `\crosstabview` command that prints the results of a query in a cross-tabulated display (Daniel Vérité)

In the `crosstab` display, data values from one query result column are placed in a grid whose column and row headers come from other query result columns.

- Add an `\errverbose` command that shows the last server error at full verbosity (Alex Shulgin)

This is useful after getting an unexpected error — you no longer need to adjust the `VERBOSITY` variable and recreate the failure in order to see error fields that are not shown by default.

- Add `\ev` and `\sv` commands for editing and showing view definitions (Petr Korobeinikov)

These are parallel to the existing `\ef` and `\sf` commands for functions.

- Add a `\gexec` command that executes a query and re-submits the result(s) as new queries (Corey Huinker)
- Allow `\pset C string` to set the table title, for consistency with `\C string` (Bruce Momjian)
- In `\pset expanded auto` mode, do not use expanded format for query results with only one column (Andreas Karlsson, Robert Haas)
- Improve the headers output by the `\watch` command (Michael Paquier, Tom Lane)

Include the `\pset title` string if one has been set, and shorten the prefabricated part of the header to be `timestamp (every Ns)`. Also, the timestamp format now obeys `psql`'s locale environment.

- Improve tab-completion logic to consider the entire input query, not only the current line (Tom Lane)

Previously, breaking a command into multiple lines defeated any tab completion rules that needed to see words on earlier lines.

- Numerous minor improvements in tab-completion behavior (Peter Eisentraut, Vik Fearing, Kevin Grittner, Kyotaro Horiguchi, Jeff Janes, Andreas Karlsson, Fujii Masao, Thomas Munro, Masahiko Sawada, Pavel Stehule)
- Add a `PROMPT` option `%p` to insert the process ID of the connected backend (Julien Rouhaud)
- Introduce a feature whereby the `CONTEXT` field of messages can be suppressed, either always or only for non-error messages (Pavel Stehule)

Printing `CONTEXT` only for errors is now the default behavior. This can be changed by setting the special variable `SHOW_CONTEXT`.

- Make `\df+` show function access privileges and parallel-safety attributes (Michael Paquier)
- SQL commands in `pgbench` scripts are now ended by semicolons, not newlines (Kyotaro Horiguchi, Tom Lane)

This change allows SQL commands in scripts to span multiple lines. Existing custom scripts will need to be modified to add a semicolon at the end of each line that does not have one already. (Doing so does not break the script for use with older versions of `pgbench`.)

- Support floating-point arithmetic, as well as some built-in functions, in expressions in backslash commands (Fabien Coelho)
- Replace `\setrandom` with built-in functions (Fabien Coelho)

The new built-in functions include `random()`, `random_exponential()`, and `random_gaussian()`, which perform the same work as `\setrandom`, but are easier to use since they can be embedded in larger expressions. Since these additions have made `\setrandom` obsolete, remove it.

- Allow invocation of multiple copies of the built-in scripts, not only custom scripts (Fabien Coelho)

This is done with the new `-b` switch, which works similarly to `-f` for custom scripts.

- Allow changing the selection probabilities (weights) for scripts (Fabien Coelho)

When multiple scripts are specified, each `pgbench` transaction randomly chooses one to execute. Formerly this was always done with uniform probability, but now different selection probabilities can be specified for different scripts.

- Collect statistics for each script in a multi-script run (Fabien Coelho)

This feature adds an intermediate level of detail to existing global and per-command statistics printouts.

- Add a `--progress-timestamp` option to report progress with Unix epoch timestamps, instead of time since the run started (Fabien Coelho)
- Allow the number of client connections (`-c`) to not be an exact multiple of the number of threads (`-j`) (Fabien Coelho)
- When the `-T` option is used, stop promptly at the end of the specified time (Fabien Coelho)

Previously, specifying a low transaction rate could cause `pgbench` to wait significantly longer than specified.

### E.33.3.11. Server Applications

- Improve error reporting during `initdb`'s post-bootstrap phase (Tom Lane)

Previously, an error here led to reporting the entire input file as the “failing query”; now just the current query is reported. To get the desired behavior, queries in `initdb`'s input files must be separated by blank lines.

- Speed up `initdb` by using just one standalone-backend session for all the post-bootstrap steps (Tom Lane)
- Improve `pg_rewind` so that it can work when the target timeline changes (Alexander Korotkov)

This allows, for example, rewinding a promoted standby back to some state of the old master's timeline.

### E.33.3.12. Source Code

- Remove obsolete `heap_formtuple/heap_modifytuple/heap_deformtuple` functions (Peter Geoghegan)
- Add macros to make `AllocSetContextCreate()` calls simpler and safer (Tom Lane)

Writing out the individual sizing parameters for a memory context is now deprecated in favor of using one of the new macros `ALLOCSET_DEFAULT_SIZES`, `ALLOCSET_SMALL_SIZES`, or `ALLOCSET_START_SMALL_SIZES`. Existing code continues to work, however.

- Unconditionally use `static inline` functions in header files (Andres Freund)

This may result in warnings and/or wasted code space with very old compilers, but the notational improvement seems worth it.

- Improve TAP testing infrastructure (Michael Paquier, Craig Ringer, Álvaro Herrera, Stephen Frost)

Notably, it is now possible to test recovery scenarios using this infrastructure.

- Make `trace_lwlocks` identify individual locks by name (Robert Haas)
- Improve `psql`'s tab-completion code infrastructure (Thomas Munro, Michael Paquier)

Tab-completion rules are now considerably easier to write, and more compact.

- Nail the `pg_shseclabel` system catalog into cache, so that it is available for access during connection authentication (Adam Brightwell)

The core code does not use this catalog for authentication, but extensions might wish to consult it.

- Restructure index access method API to hide most of it at the C level (Alexander Korotkov, Andrew Gierth)

This change modernizes the index AM API to look more like the designs we have adopted for foreign data wrappers and tablesample handlers. This simplifies the C code and makes it much more practical to define index access methods in installable extensions. A consequence is that most of the columns of the `pg_am` system catalog have disappeared. New inspection functions have been added to allow SQL queries to determine index AM properties that used to be discoverable from `pg_am`.

- Add `pg_init_privs` system catalog to hold original privileges of initdb-created and extension-created objects (Stephen Frost)

This infrastructure allows `pg_dump` to dump changes that an installation may have made in privileges attached to system objects. Formerly, such changes would be lost in a dump and reload, but now they are preserved.

- Change the way that extensions allocate custom `LWLocks` (Amit Kapila, Robert Haas)

The `RequestAddinLWLocks()` function is removed, and replaced by `RequestNamedLWLockTranche()`. This allows better identification of custom `LWLocks`, and is less error-prone.

- Improve the isolation tester to allow multiple sessions to wait concurrently, allowing testing of deadlock scenarios (Robert Haas)
- Introduce extensible node types (KaiGai Kohei)

This change allows FDWs or custom scan providers to store data in a plan tree in a more convenient format than was previously possible.

- Make the planner deal with post-scan/join query steps by generating and comparing `Paths`, replacing a lot of ad-hoc logic (Tom Lane)

This change provides only marginal user-visible improvements today, but it enables future work on a lot of upper-planner improvements that were impractical to tackle using the old code structure.

- Support partial aggregation (David Rowley, Simon Riggs)

This change allows the computation of an aggregate function to be split into separate parts, for example so that parallel worker processes can cooperate on computing an aggregate. In future it might allow aggregation across local and remote data to occur partially on the remote end.

- Add a generic command progress reporting facility (Vinayak Pokale, Rahila Syed, Amit Langote, Robert Haas)
- Separate out `psql`'s flex lexer to make it usable by other client programs (Tom Lane, Kyotaro Horiguchi)

This eliminates code duplication for programs that need to be able to parse SQL commands well enough to identify command boundaries. Doing that in full generality is more painful than one could wish, and up to now only `psql` has really gotten it right among our supported client programs.

A new source-code subdirectory `src/fe_utils/` has been created to hold this and other code that is shared across our client programs. Formerly such sharing was accomplished by symbolic linking or copying source files at build time, which was ugly and required duplicate compilation.

- Introduce `WaitEventSet` API to allow efficient waiting for event sets that usually do not change from one wait to the next (Andres Freund, Amit Kapila)
- Add a generic interface for writing WAL records (Alexander Korotkov, Petr Jelínek, Markus Nullmeier)

This change allows extensions to write WAL records for changes to pages using a standard layout. The problem of needing to replay WAL without access to the extension is solved by having generic replay code. This allows extensions to implement, for example, index access methods and have WAL support for them.

- Support generic WAL messages for logical decoding (Petr Jelínek, Andres Freund)

This feature allows extensions to insert data into the WAL stream that can be read by logical-decoding plugins, but is not connected to physical data restoration.

- Allow SP-GiST operator classes to store an arbitrary “traversal value” while descending the index (Alexander Lebedev, Teodor Sigaev)

This is somewhat like the “reconstructed value”, but it could be any arbitrary chunk of data, not necessarily of the same data type as the indexed column.

- Introduce a `LOG_SERVER_ONLY` message level for `ereport()` (David Steele)

This level acts like `LOG` except that the message is never sent to the client. It is meant for use in auditing and similar applications.

- Provide a `Makefile` target to build all generated headers (Michael Paquier, Tom Lane)

`submake-generated-headers` can now be invoked to ensure that generated backend header files are up-to-date. This is useful in subdirectories that might be built “standalone”.

- Support OpenSSL 1.1.0 (Andreas Karlsson, Heikki Linnakangas)

### E.33.3.13. Additional Modules

- Add configuration parameter `auto_explain.sample_rate` to allow `contrib/auto_explain` to capture just a configurable fraction of all queries (Craig Ringer, Julien Rouhaud)

This allows reduction of overhead for heavy query traffic, while still getting useful information on average.

- Add `contrib/bloom` module that implements an index access method based on Bloom filtering (Teodor Sigaev, Alexander Korotkov)

This is primarily a proof-of-concept for non-core index access methods, but it could be useful in its own right for queries that search many columns.

- In `contrib/cube`, introduce distance operators for cubes, and support kNN-style searches in GiST indexes on cube columns (Stas Kelvich)
- Make `contrib/hstore`'s `hstore_to_jsonb_loose()` and `hstore_to_json_loose()` functions agree on what is a number (Tom Lane)

Previously, `hstore_to_jsonb_loose()` would convert numeric-looking strings to JSON numbers, rather than strings, even if they did not exactly match the JSON syntax specification for numbers. This was inconsistent with `hstore_to_json_loose()`, so tighten the test to match the JSON syntax.

- Add selectivity estimation functions for `contrib/intarray` operators to improve plans for queries using those operators (Yury Zhuravlev, Alexander Korotkov)
- Make `contrib/pageinspect`'s `heap_page_items()` function show the raw data in each tuple, and add new functions `tuple_data_split()` and `heap_page_item_attrs()` for inspection of individual tuple fields (Nikolay Shaplov)
- Add an optional S2K iteration count parameter to `contrib/pgcrypto`'s `pgp_sym_encrypt()` function (Jeff Janes)
- Add support for “word similarity” to `contrib/pg_trgm` (Alexander Korotkov, Artur Zakirov)

These functions and operators measure the similarity between one string and the most similar single word of another string.

- Add configuration parameter `pg_trgm.similarity_threshold` for `contrib/pg_trgm`'s similarity threshold (Artur Zakirov)

This threshold has always been configurable, but formerly it was controlled by special-purpose functions `set_limit()` and `show_limit()`. Those are now deprecated.

- Improve `contrib/pg_trgm`'s GIN operator class to speed up index searches in which both common and rare keys appear (Jeff Janes)
- Improve performance of similarity searches in `contrib/pg_trgm` GIN indexes (Christophe Fornaroli)
- Add `contrib/pg_visibility` module to allow examining table visibility maps (Robert Haas)
- Add `ssl_extension_info()` function to `contrib/sslinfo`, to print information about SSL extensions present in the X509 certificate used for the current connection (Dmitry Voronin)

#### **E.33.3.13.1. `postgres_fdw`**

- Allow extension-provided operators and functions to be sent for remote execution, if the extension is whitelisted in the foreign server's options (Paul Ramsey)

Users can enable this feature when the extension is known to exist in a compatible version in the remote database. It allows more efficient execution of queries involving extension operators.

- Consider performing sorts on the remote server (Ashutosh Bapat)
- Consider performing joins on the remote server (Shigeru Hanada, Ashutosh Bapat)
- When feasible, perform `UPDATE` or `DELETE` entirely on the remote server (Etsuro Fujita)

Formerly, remote updates involved sending a `SELECT FOR UPDATE` command and then updating or deleting the selected rows one-by-one. While that is still necessary if the operation requires any local processing, it can now be done remotely if all elements of the query are safe to send to the remote server.

- Allow the fetch size to be set as a server or table option (Corey Huinker)

Formerly, `postgres_fdw` always fetched 100 rows at a time from remote queries; now that behavior is configurable.

- Use a single foreign-server connection for local user IDs that all map to the same remote user (Ashutosh Bapat)
- Transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)

Previously, a local query cancellation request did not cause an already-sent remote query to terminate early.

## **E.34. Release 9.5.10**

**Release date:** 2017-11-09

This release contains a variety of fixes from 9.5.9. For information about new features in the 9.5 major release, see Section E.44.

### **E.34.1. Migration to Version 9.5.10**

A dump/restore is not required for those running 9.5.X.

However, if you use BRIN indexes, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.5.8, see Section E.36.

### **E.34.2. Changes**

- Ensure that `INSERT ... ON CONFLICT DO UPDATE` checks table permissions and RLS policies in all cases (Dean Rasheed)

The update path of `INSERT ... ON CONFLICT DO UPDATE` requires `SELECT` permission on the columns of the arbiter index, but it failed to check for that in the case of an arbiter specified by constraint name. In addition, for a table with row level security enabled, it failed to check updat-

ed rows against the table's `SELECT` policies (regardless of how the arbiter index was specified). (CVE-2017-15099)

- Fix crash due to rowtype mismatch in `json{b}_populate_recordset()` (Michael Paquier, Tom Lane)

These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn't, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

Previously, the postmaster log file was opened while still running as `root`. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix BRIN index summarization to handle concurrent table extension correctly (Álvaro Herrera)

Previously, a race condition allowed some table rows to be omitted from the index. It may be necessary to reindex existing BRIN indexes to recover from past occurrences of this problem.

- Fix possible failures during concurrent updates of a BRIN index (Tom Lane)

These race conditions could result in errors like “invalid index offnum” or “inconsistent range map”.

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)
- Fix `json_build_array()`, `json_build_object()`, and their `jsonb` equivalents to handle explicit `VARIADIC` arguments correctly (Michael Paquier)
- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range's subtype has hash support. This does not affect any of the built-in range types, since they're all hashable anyway.

- Correctly ignore `RelabelType` expression nodes when determining relation distinctness (David Rowley)

This allows the intended optimization to occur when a subquery has a result column of type `varchar`.

- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid SIGBUS crash on Linux when a DSM memory request exceeds the space available in tmpfs (Thomas Munro)
- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Allow `COPY'S FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)

This case was unintentionally broken by a previous bug fix.

- Correctly restore the umask setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)
- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)
- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)
- Fix `pg_basebackup`'s matching of tablespace paths to canonicalize both paths before comparing (Michael Paquier)

This is particularly helpful on Windows.

- Fix `libpq` to not require user's home directory to exist (Tom Lane)

In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- Fix `libpq` to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)
- Fix `ecpg`'s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
- In `ecpglib`, correctly handle backslashes in string literals depending on whether `standard_conforming_strings` is set (Tsunakawa Takayuki)
- Make `ecpglib`'s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Fix missing temp-install prerequisites for `check`-like Make targets (Noah Misch)

Some non-default test procedures that are meant to work like `make check` failed to ensure that the temporary installation was up to date.

- Sync our copy of the timezone library with IANA release `tzcode2017c` (Tom Lane)

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to `tzdata` release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

## E.35. Release 9.5.9

**Release date:** 2017-08-31

This release contains a small number of fixes from 9.5.8. For information about new features in the 9.5 major release, see Section E.44.

### E.35.1. Migration to Version 9.5.9

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.8, see Section E.36.

## E.35.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in `psql`:

```
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
    SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
           CAST(grantee.rolname AS sql_identifier) AS grantee,
           CAST(current_database() AS sql_identifier) AS table_catalog,
           CAST(nc.nspname AS sql_identifier) AS table_schema,
           CAST(c.relname AS sql_identifier) AS table_name,
           CAST(c.prtype AS character_data) AS privilege_type,
           CAST(
               CASE WHEN
                   -- object owner always has grant options
                   pg_has_role(grantee.oid, c.relowner, 'USAGE')
                   OR c.grantable
                   THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
           CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no)
AS with_hierarchy

    FROM (
        SELECT oid, relname, relnamespace, relkind, relowner,
               (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
        ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee,
               prtype, grantable),
        pg_namespace nc,
        pg_authid u_grantor,
        (
            SELECT oid, rolname FROM pg_authid
            UNION ALL
            SELECT 0::oid, 'PUBLIC'
        ) AS grantee (oid, rolname)

    WHERE c.relnamespace = nc.oid
           AND c.relkind IN ('r', 'v', 'f')
           AND c.grantee = grantee.oid
           AND c.grantor = u_grantor.oid
           AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE',
                           'REFERENCES', 'TRIGGER')
           AND (pg_has_role(u_grantor.oid, 'USAGE')
                OR pg_has_role(grantee.oid, 'USAGE')
                OR grantee.rolname = 'PUBLIC');
```

This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of `SIGTERM`) that occurs while trying to execute a `ROLLBACK` of a failed transaction (Tom Lane)

This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain `ALTER` commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Fix crash in `pg_restore` when using parallel mode and using a list file to select a subset of items to restore (Fabrízio de Royes Mello)
- Change `ecpg`'s parser to allow `RETURNING` clauses without attached C variables (Michael Meskes)

This allows `ecpg` programs to contain SQL constructs that use `RETURNING` internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T` is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.

- Fix `make check` to behave correctly when invoked via a non-GNU `make` program (Thomas Munro)

## E.36. Release 9.5.8

**Release date:** 2017-08-10

This release contains a variety of fixes from 9.5.7. For information about new features in the 9.5 major release, see Section E.44.

### E.36.1. Migration to Version 9.5.8

A dump/restore is not required for those running 9.5.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.5.7, see Section E.37.

### E.36.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly `initdb`'d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you'll still need a restart.)
2. In *each* database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;  
CREATE OR REPLACE VIEW pg_user_mappings AS  
SELECT
```

```

U.oid      AS umid,
S.oid      AS srvid,
S.srvname  AS srvname,
U.umuser   AS umuser,
CASE WHEN U.umuser = 0 THEN
    'public'
ELSE
    A.rolname
END AS username,
CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
    AND (pg_has_role(S.srvowner, 'USAGE')
        OR has_server_privilege(S.oid, 'USAGE')))
    OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
    OR (SELECT rolsuper FROM pg_authid WHERE rolname =
current_user)
    THEN U.umoptions
    ELSE NULL END AS umoptions
FROM pg_user_mapping U
    LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
    pg_foreign_server S ON (U.umserver = S.oid);

```

- Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing `template0`, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

- Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.
- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

`libpq` ignores empty password specifications, and does not transmit them to the server. So, if a user's password has been set to the empty string, it's impossible to log in with that password via `psql` or other `libpq`-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-`libpq`-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, `md5`, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)
  - Make `lo_put()` check for `UPDATE` privilege on the target large object (Tom Lane, Michael Paquier)

`lo_put()` should surely require the same permissions as `lowrite()`, but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)
  - Correct the documentation about the process for upgrading standby servers with `pg_upgrade` (Bruce Momjian)

The previous documentation instructed users to start/stop the primary server after running `pg_upgrade` but before syncing the standby servers. This sequence is unsafe.
  - Fix concurrent locking of tuple update chains (Álvaro Herrera)

If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and con-

clude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)
- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Kopolov)
- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
- Prevent sending SSL session tickets to clients (Tom Lane)

This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting `tcp_keepalives_idle` on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector's receive buffer size is at least 100KB (Tom Lane)

This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an `XLOG_SWITCH` WAL record (Andres Freund)
- Fix walsender to exit promptly when client requests shutdown (Tom Lane)
- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)

This resulted in temporary files consuming excessive disk space.

- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)

The previous algorithm was infeasibly expensive on a server with a lot of open transactions.

- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)
- Reduce overhead in processing syscache invalidation events (Tom Lane)

This is particularly helpful for logical decoding, which triggers frequent cache invalidation.

- Fix cases where an `INSERT` or `UPDATE` assigns to more than one element of a column that is of domain-over-array type (Tom Lane)

- Allow window functions to be used in sub-SELECTs that are within the arguments of an aggregate function (Tom Lane)
- Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)

Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.

- Fix dangling pointer in ALTER TABLE when there is a comment on a constraint belonging to the table (David Rowley)

Re-applying the comment to the reconstructed constraint could fail with a weird error message, or even crash.

- Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function's argument or return type from opaque to the correct type (Heikki Linnakangas)

CREATE TYPE updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent DROP TYPE to leave broken function definitions behind.

- Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as regprocedurein() (Tom Lane)

Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant #define symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix pg\_dump and pg\_restore to emit REFRESH MATERIALIZED VIEW commands last (Tom Lane)

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Improve pg\_dump/pg\_restore's reporting of error conditions originating in zlib (Vladimir Kunschikov, Alvaro Herrera)
- Fix pg\_dump with the --clean option to drop event triggers as expected (Tom Lane)

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix pg\_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

- Fix `pg_dump` output to stdout on Windows (Kuntal Ghosh)

A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a `NATURAL LEFT JOIN` with no common columns (Tom Lane)
- Fix dumping of function expressions in the `FROM` clause in cases where the expression does not de-parse into something that looks like a function call (Tom Lane)
- Fix `pg_basebackup` output to stdout on Windows (Haribabu Kommi)

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_rewind` to correctly handle files exceeding 2GB (Kuntal Ghosh, Michael Paquier)

Ordinarily such files won't appear in PostgreSQL data directories, but they could be present in some cases.

- Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

- Fix `pg_xlogdump`'s computation of WAL record length (Andres Freund)
- In `postgres_fdw`, re-establish connections to remote servers after `ALTER SERVER` or `ALTER USER MAPPING` commands (Kyotaro Horiguchi)

This ensures that option changes affecting connection parameters will be applied promptly.

- In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)

This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Increase `MAX_SYSCACHE_CALLBACKS` to provide more room for extensions (Tom Lane)
- Always use `-fPIC`, not `-fpic`, when building shared libraries with `gcc` (Tom Lane)

This supports larger extension libraries on platforms where it makes a difference.

- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the `openssl` library is not within a `VC` subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for `libxml2` header files (Andrew Dunstan)

This fixes a former need to move things around in standard Windows installations of `libxml2`.

- In MSVC builds, recognize a Tcl library that is named `tc186.lib` (Noah Misch)
- In MSVC builds, honor `PROVE_FLAGS` settings on `vc regress.pl`'s command line (Andrew Dunstan)

## E.37. Release 9.5.7

**Release date:** 2017-05-11

This release contains a variety of fixes from 9.5.6. For information about new features in the 9.5 major release, see Section E.44.

### E.37.1. Migration to Version 9.5.7

A dump/restore is not required for those running 9.5.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.5.6, see Section E.38.

### E.37.2. Changes

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.36.

- Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator's implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

- Restore libpq's recognition of the `PGREQUIRESSL` environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than `PGSSLMODE`, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

- Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

- Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

- Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Avoid possible crash in `walsender` due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)
- Fix possible crash when rescanning a nearest-neighbor index-only scan on a GiST index (Tom Lane)
- Fix postmaster's handling of `fork()` failure for a background worker process (Tom Lane)

Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

- Fix crash or wrong answers when a `GROUPING SETS` column's data type is hashable but not sortable (Pavan Deolasee)
- Avoid applying “physical targetlist” optimization to custom scans (Dmitry Ivanov, Tom Lane)

This optimization supposed that retrieving all columns of a tuple is inexpensive, which is true for ordinary Postgres tuples; but it might not be the case for a custom scan provider.

- Use the correct sub-expression when applying a `FOR ALL` row-level-security policy (Stephen Frost)

In some cases the `WITH CHECK` restriction would be applied when the `USING` restriction is more appropriate.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Avoid dangling pointer in `COPY ... TO` when row-level security is active for the source table (Tom Lane)

Usually this had no ill effects, but sometimes it would cause unexpected errors or crashes.

- Avoid accessing an already-closed `relcache` entry in `CLUSTER` and `VACUUM FULL` (Tom Lane)

With some bad luck, this could lead to indexes on the target relation getting rebuilt with the wrong persistence setting.

- Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
- Fix integer-overflow problems in `interval` comparison (Kyotaro Horiguchi, Tom Lane)

The comparison operators for type `interval` could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

- Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

- Fix roundoff problems in `float8_timestampz()` and `make_interval()` (Tom Lane)

These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

- Fix `pg_get_object_address()` to handle members of operator families correctly (Álvaro Herrera)
- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)
- Reduce memory management overhead for contexts containing many large blocks (Tom Lane)
- Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn't accessible, so that no logging happens at all.

- Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)
- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -l`'s purposes.

- Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)

Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in `contrib/adminpack`'s `pg_file_write()` function (Noah Misch)

Notably, it failed to detect errors reported by `fclose()`.

- In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix `contrib/pg_trgm`'s extraction of trigrams from regular expressions (Tom Lane)

In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In `contrib/postgres_fdw`, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)

Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.

- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release `tzcode2017b` (Tom Lane)

This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to `tzdata` release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the `posixrules` file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the `US/Eastern` zone. If you don't want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

## E.38. Release 9.5.6

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.5.5. For information about new features in the 9.5 major release, see Section E.44.

### E.38.1. Migration to Version 9.5.6

A dump/restore is not required for those running 9.5.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.5.5, see Section E.39.

### E.38.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)

Backends failed to account for this snapshot when advertising their oldest xmin, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Fix incorrect WAL logging for BRIN indexes (Kuntal Ghosh)

The WAL record emitted for a BRIN “revmap” page when moving an index tuple to a different page was incorrect. Replay would make the related portion of the index useless, forcing it to be recomputed.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

Previously, this was skipped when `wal_level = minimal`, but actually it's necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

This change avoids substantial replication delays that sometimes occurred while replaying such operations.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)
- Ensure that hot standby feedback works correctly when it's enabled at standby server start (Ants Aasma, Craig Ringer)
- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)
- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint's deferrability properties with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)

This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

This avoids “could not find trigger *NNN*” or “relation *NNN* has no triggers” errors.

- Fix `ALTER TABLE ... SET DATA TYPE ... USING` when child table has different column ordering than the parent (Álvaro Herrera)

Failure to adjust the column numbering in the `USING` expression led to errors, typically “attribute *N* has wrong type”.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)

The OID column should be treated the same as regular user columns in this case, but it wasn't, leading to odd behavior in later inheritance changes.

- Fix `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)

Previously the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)

The wrong catalog OID was reported to extensions such as logical decoding.

- Fix commit timestamp mechanism to not fail when queried about the special XIDs `FrozenTransactionId` and `BootstrapTransactionId` (Craig Ringer)
- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Fix incorrect use of view reloptions as regular table reloptions (Tom Lane)

The symptom was spurious “ON CONFLICT is not supported on table ... used as a catalog table” errors when the target of `INSERT ... ON CONFLICT` is a view with cascade option.

- Fix incorrect “target lists can have at most *N* entries” complaint when using `ON CONFLICT` with wide tables (Tom Lane)
- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)

This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)

This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don't share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)

Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&' ... '`) or Unicode identifier (`U&" ... "`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)
- Fix `ts_rewrite()`'s handling of nested NOT operators (Tom Lane)
- Improve speed of user-defined aggregates that use `array_append()` as transition function (Tom Lane)
- Fix `array_fill()` to handle empty arrays properly (Tom Lane)
- Fix possible crash in `array_position()` or `array_positions()` when processing arrays of records (Junseok Yang)
- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)

The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)

This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Disable transform that attempted to remove no-op AT TIME ZONE conversions (Tom Lane)

This resulted in wrong answers when the simplified expression was used in an index condition.

- Avoid discarding `interval-to-interval` casts that aren't really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Fix bugs in transmitting GUC parameter values to parallel workers (Michael Paquier, Tom Lane)
- Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)
- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix `pg_restore` with `--create --if-exists` to behave more sanely if an archive contains unrecognized `DROP` commands (Tom Lane)

This doesn't fix any live bug, but it may improve the behavior in future if `pg_restore` is used with an archive generated by a later `pg_dump` version.

- Fix `pg_basebackup`'s rate limiting in the presence of slow I/O (Antonin Houska)

If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

- Fix `pg_basebackup`'s handling of symlinked `pg_stat_tmp` and `pg_replslot` subdirectories (Magnus Hagander, Michael Paquier)
- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)
- Fix possible mishandling of expanded arrays in domain check constraints and `CASE` execution (Tom Lane)

It was possible for a PL/pgSQL function invoked in these contexts to modify or even delete an array value that needs to be preserved for additional operations.

- Fix nested uses of PL/pgSQL functions in contexts such as domain check constraints evaluated during assignment to a PL/pgSQL variable (Tom Lane)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)

This matches the (previously undocumented) behavior of PL/Tcl's `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn't a real column named that.

- Allow DOS-style line endings in `~/.pgpass` files, even on Unix (Vik Fearing)

This change simplifies use of the same password file across Unix and Windows machines.

- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix `psql`'s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)

Previously, such a setting caused output intended for the pager to vanish entirely.

- Improve `contrib/dblink`'s reporting of low-level `libpq` errors, such as out-of-memory (Joe Conway)
- Teach `contrib/dblink` to ignore irrelevant server options when it uses a `contrib/postgres_fdw` foreign server as the source of connection options (Corey Huinker)

Previously, if the foreign server object had options that were not also `libpq` connection options, an error occurred.

- Fix portability problems in `contrib/pageinspect`'s functions for GIN indexes (Peter Eisentraut, Tom Lane)
- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release `tzcode2016j` (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn't support hard links.

- Update time zone data files to `tzdata` release 2016j for DST law changes in northern Cyprus (adding a new zone `Asia/Famagusta`), Russia (adding a new zone `Europe/Saratov`), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

## E.39. Release 9.5.5

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.5.4. For information about new features in the 9.5 major release, see Section E.44.

### E.39.1. Migration to Version 9.5.5

A dump/restore is not required for those running 9.5.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.5.2, see Section E.42.

### E.39.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access

pages that have been truncated away from the relation itself, typically producing errors like “could not read block `xxx`: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at [https://wiki.postgresql.org/wiki/Free\\_Space\\_Map\\_Problems](https://wiki.postgresql.org/wiki/Free_Space_Map_Problems).

- Fix incorrect creation of GIN index WAL records on big-endian machines (Tom Lane)

The typical symptom was “unexpected GIN leaf action” errors during WAL replay.

- Fix `SELECT FOR UPDATE/SHARE` to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)

In 9.5 and later, the `SELECT` would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix deletion of speculatively inserted TOAST tuples when backing out of `INSERT ... ON CONFLICT` (Oskari Saarenmaa)

In the race condition where two transactions try to insert conflicting tuples at about the same time, the loser would fail with an “attempted to delete invisible tuple” error if its insertion included any TOAST'ed fields.

- Don't throw serialization errors for self-conflicting insertions in `INSERT ... ON CONFLICT` (Thomas Munro, Peter Geoghegan)
- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)

The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix query-lifespan memory leak in a bulk `UPDATE` on a table with a `PRIMARY KEY` or `REPLICA IDENTITY` index (Tom Lane)
- Fix `COPY` with a column name list from a table that has row-level security enabled (Adam Brightwell)
- Fix `EXPLAIN` to emit valid XML when `track_io_timing` is on (Markus Winand)

Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- Suppress printing of zeroes for unmeasured times in `EXPLAIN` (Maksim Milyutin)

Certain option combinations resulted in printing zero values for times that actually aren't ever measured in that combination. Our general policy in `EXPLAIN` is not to print such fields at all, so do that consistently in all cases.

- Fix statistics update for `TRUNCATE` in a prepared transaction (Stas Kelvich)
- Fix timeout length when `VACUUM` is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing `VACUUM` to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- Show a sensible value in `pg_settings.unit` for `min_wal_size` and `max_wal_size` (Tom Lane)
- Remove artificial restrictions on the values accepted by `numeric_in()` and `numeric_recv()` (Tom Lane)

We allow numeric values up to the limit of the storage format (more than `1e100000`), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Preserve commit timestamps across server restart (Julien Rouhaud, Craig Ringer)

With `track_commit_timestamp` turned on, old commit timestamps became inaccessible after a clean server restart.

- Fix logical WAL decoding to work properly when a subtransaction's WAL output is large enough to spill to disk (Andres Freund)
- Fix possible sorting error when aborting use of abbreviated keys (Peter Geoghegan)

In the worst case, this could result in a corrupt btree index, which would need to be rebuilt using `REINDEX`. However, the situation is believed to be rare.

- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
- Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)

This can't do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn't designed with this situation in mind.

- Properly initialize replication slot state when recycling a previously-used slot (Michael Paquier)

This failure to reset all of the fields of the slot could prevent `VACUUM` from removing dead tuples.

- Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)

This avoids possible failures during `munmap()` on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.

- Use a more random value for the dynamic shared memory control segment's ID (Robert Haas, Tom Lane)

Previously, the same value would be chosen every time, because it was derived from `random()` but `srandom()` had not yet been called. While relatively harmless, this was not the intended behavior.

- On Windows, retry creation of the dynamic shared memory control segment after an access-denied error (Kyotaro Horiguchi, Amit Kapila)

Windows sometimes returns `ERROR_ACCESS_DENIED` rather than `ERROR_ALREADY_EXISTS` when there is an existing segment. This led to postmaster startup failure due to believing that the former was an unrecoverable error.

- Fix PL/pgSQL to not misbehave with parameters and local variables of type `int2vector` or `oidvector` (Tom Lane)
- Don't try to share SSL contexts across multiple connections in `libpq` (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

- Make `ecpg's --help` and `--version` options work consistently with our other executables (Haribabu Kommi)
- Fix `pgbench's` calculation of average latency (Fabien Coelho)

The calculation was incorrect when there were `\sleep` commands in the script, or when the test duration was specified in number of transactions rather than total time.

- In `pg_upgrade`, check library loadability in name order (Tom Lane)

This is a workaround to deal with cross-extension dependencies from language transform modules to their base language and data type modules.

- In `pg_dump`, never dump range constructor functions (Tom Lane)

This oversight led to `pg_upgrade` failures with extensions containing range types, due to duplicate creation of the constructor functions.

- In `pg_dump` with `-C`, suppress `TABLESPACE` clause of `CREATE DATABASE` if `--no-tablespaces` is specified (Tom Lane)
- Make `pg_receivexlog` work correctly with `--synchronous` without slots (Gabriele Bartolini)
- Disallow specifying both `--source-server` and `--source-target` options to `pg_rewind` (Michael Banck)
- Make `pg_rewind` turn off `synchronous_commit` in its session on the source server (Michael Banck, Michael Paquier)

This allows `pg_rewind` to work even when the source server is using synchronous replication that is not working for some reason.

- In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Haggander)

This allows for a possible delay in the server's creation of the next segment.

- Fix `pg_xlogdump` to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
- Fix `contrib/pg_buffercache` to work when `shared_buffers` exceeds 256GB (KaiGai Kohei)
- Fix `contrib/intarray/bench/bench.pl` to print the results of the `EXPLAIN` it does when given the `-e` option (Daniel Gustafsson)
- Support OpenSSL 1.1.0 (Heikki Linnakangas)
- Install TAP test infrastructure so that it's available for extension testing (Craig Ringer)

When PostgreSQL has been configured with `--enable-tap-tests`, "make install" will now install the Perl support files for TAP testing where PGXS can find them. This allows non-core extensions to use `$(prove_check)` without extra tests.

- In MSVC builds, include `pg_recvlogical` in a client-only installation (MauMau)
- Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in `tzdata` release 2016f and seem likely to do again

in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbrevs` view to fail altogether.

- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, `AMT` is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the `Default` abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

## E.40. Release 9.5.4

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.5.3. For information about new features in the 9.5 major release, see Section E.44.

### E.40.1. Migration to Version 9.5.4

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.2, see Section E.42.

### E.40.2. Changes

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function's body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs' handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in `vacuumdb` and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a `conninfo` string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in `psql`'s `\connect` and `\password` commands to match the documentation.

Introduce a new `-reuse-previous` option in `psql`'s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a `conninfo` string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

`pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that `IS NULL` should return `TRUE` for a row of all null values (thus `ROW(NULL, NULL) IS NULL` yields `TRUE`), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL, NULL)) IS NULL` yields `FALSE`). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing `TRUE` in both cases), and `contrib/postgres_fdw` could produce remote queries that misbehaved similarly.

- Fix “unrecognized node type” error for `INSERT ... ON CONFLICT` within a recursive CTE (a `WITH` item) (Peter Geoghegan)
- Fix `INSERT ... ON CONFLICT` to successfully match index expressions or index predicates that are simplified during the planner's expression preprocessing phase (Tom Lane)
- Correctly handle violations of exclusion constraints that apply to the target table of an `INSERT ... ON CONFLICT` command, but are not one of the selected arbiter indexes (Tom Lane)

Such a case should raise a normal constraint-violation error, but it got into an infinite loop instead.

- Fix `INSERT ... ON CONFLICT` to not fail if the target table has a unique index on `OID` (Tom Lane)
- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)
- Prevent crash in `close_ps()` (the `point ## lseg` operator) for NaN input coordinates (Tom Lane)

Make it return `NULL` instead of crashing.

- Avoid possible crash in `pg_get_expr()` when inconsistent values are passed to it (Michael Paquier, Thomas Munro)
- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)

This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn't exist yet.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

Previously, these cases locked the target tuple (by setting its `XMAX`) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Fix hint bit update during WAL replay of row locking operations (Andres Freund)

The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)
- Make sure “expanded” datums returned by a plan node are read-only (Tom Lane)

This avoids failures in some cases where the result of a lower plan node is referenced in multiple places in upper nodes. So far as core PostgreSQL is concerned, only array values returned by PL/pgSQL functions are at risk; but extensions might use expanded datums for other things.

- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)
- Prevent unintended waits for the receiver in WAL sender processes (Kyotaro Horiguchi)
- Fix possible loss of large subtransactions in logical decoding (Petru-Florin Mihancea)
- Fix failure of logical decoding when a subtransaction contains no actual changes (Marko Tiikkaja, Andrew Gierth)
- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)

The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)
- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

Some cases in `VACUUM` unnecessarily caused an `XID` to be assigned to the current transaction. Normally this is negligible, but if one is up against the `XID` wraparound limit, consuming more `XIDs` during anti-wraparound vacuums is a very bad thing.

- Prevent possible failure when vacuuming multixact IDs in an installation that has been `pg_upgrade'd` from pre-9.3 (Andrew Gierth, Álvaro Herrera)

The usual symptom of this bug is errors like “MultiXactId `NNN` has not been created yet -- apparent wraparound”.

- When a manual `ANALYZE` specifies a column list, don't reset the table's `changes_since_analyze` counter (Tom Lane)

If we're only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix `ANALYZE`'s overestimation of `n_distinct` for a unique or nearly-unique column with many null entries (Tom Lane)

The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

Normally this isn't much of a problem because the vacuum doesn't take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Fix bug in b-tree mark/restore processing (Kevin Grittner)

This error could lead to incorrect join results or assertion failures in a merge join whose inner source node is a b-tree indexscan.

- Avoid duplicate buffer lock release when abandoning a b-tree index page deletion attempt (Tom Lane)

This mistake prevented `VACUUM` from completing in some cases involving corrupt b-tree indexes.

- Fix building of large (bigger than `shared_buffers`) hash indexes (Tom Lane)

The code path used for large indexes contained a bug causing incorrect hash values to be inserted into the index, so that subsequent index searches always failed, except for tuples inserted into the index after the initial build.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
- Fix possible crash during a nearest-neighbor (`ORDER BY distance`) indexscan on a `contrib/btree_gist` index on an `interval` column (Peter Geoghegan)
- Fix “PANIC: failed to add BRIN tuple” error when attempting to update a BRIN index entry (Álvaro Herrera)
- Fix possible crash during background worker shutdown (Dmitry Ivanov)
- Fix PL/pgSQL's handling of the `INTO` clause within `IMPORT FOREIGN SCHEMA` commands (Tom Lane)
- Fix `contrib/btree_gin` to handle the smallest possible `bigint` value correctly (Peter Eisentraut)
- Teach `libpq` to correctly decode server version from future servers (Peter Eisentraut)

It's planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that `PQserverVersion()` returns the correct value for such cases.

- Fix `ecpg`'s code for `unsigned long long` array elements (Michael Meskes)
- In `pg_dump` with both `-c` and `-C` options, avoid emitting an unwanted `CREATE SCHEMA public` command (David Johnston, Tom Lane)
- Improve handling of SIGTERM/control-C in parallel `pg_dump` and `pg_restore` (Tom Lane)

Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a `CREATE INDEX`.

- Fix error reporting in parallel `pg_dump` and `pg_restore` (Tom Lane)

Previously, errors reported by `pg_dump` or `pg_restore` worker processes might never make it to the user's console, because the messages went through the master process, and there were various deadlock scenarios that would prevent the master process from passing on the messages. Instead, just print everything to `stderr`. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.

- Ensure that parallel `pg_dump` or `pg_restore` on Windows will shut down properly after an error (Kyotaro Horiguchi)

Previously, it would report the error, but then just sit until manually stopped by the user.

- Make parallel `pg_dump` fail cleanly when run against a standby server (Magnus Hagander)

This usage is not supported unless `--no-synchronized-snapshots` is specified, but the error was not handled very well.

- Make `pg_dump` behave better when built without `zlib` support (Kyotaro Horiguchi)

It didn't work right for parallel dumps, and emitted some rather pointless warnings in other cases.

- Make `pg_basebackup` accept `-Z 0` as specifying no compression (Fujii Masao)
- Fix `makefiles`' rule for building AIX shared libraries to be safe for parallel `make` (Noah Misch)
- Fix TAP tests and MSVC scripts to work when build directory's path name contains spaces (Michael Paquier, Kyotaro Horiguchi)
- Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)

On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.

- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA's tzcode release 2016c (Tom Lane)

This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

## E.41. Release 9.5.3

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.5.2. For information about new features in the 9.5 major release, see Section E.44.

### E.41.1. Migration to Version 9.5.3

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.2, see Section E.42.

### E.41.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it's clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It's possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any  $N$ -way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)
- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

Given a three-or-more-way equivalence class of variables, such as  $X.X = Y.Y = Z.Z$ , it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn't satisfy the `WHERE` clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix corner-case parser failures occurring when `operator_precedence_warning` is turned on (Tom Lane)

An example is that `SELECT (ARRAY[])::text[]` gave an error, though it worked without the parentheses.

- Fix query-lifespan memory leak in GIN index scans (Julien Rouhaud)
- Fix query-lifespan memory leak and potential index corruption hazard in GIN index insertion (Tom Lane)

The memory leak would typically not amount to much in simple queries, but it could be very substantial during a large GIN index build with high `maintenance_work_mem`.

- Fix possible misbehavior of `TH`, `th`, and `Y,YYY` format codes in `to_timestamp()` (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the `array` argument of a `value operator ANY (array)` construct is a sub-SELECT (Tom Lane)
- Disallow newlines in `ALTER SYSTEM` parameter values (Tom Lane)

The configuration-file parser doesn't support embedded newlines in string literals, so we mustn't allow them in values to be inserted by `ALTER SYSTEM`.

- Fix `ALTER TABLE ... REPLICA IDENTITY USING INDEX` to work properly if an index on OID is selected (David Rowley)
- Avoid possible misbehavior after failing to remove a tablespace symlink (Tom Lane)
- Fix crash in logical decoding on alignment-picky platforms (Tom Lane, Andres Freund)

The failure occurred only with a transaction large enough to spill to disk and a primary-key change within that transaction.

- Avoid repeated requests for feedback from receiver while shutting down walsender (Nick Cleaton)
- Make `pg_regress` use a startup timeout from the `PGCTLTIMEOUT` environment variable, if that's set (Tom Lane)

This is for consistency with a behavior recently added to `pg_ctl`; it eases automated testing on slow machines.

- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.

- Fix `pg_upgrade` to not fail when new-cluster TOAST rules differ from old (Tom Lane)

`pg_upgrade` had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can't get along fine without a TOAST table if that was okay according to the old version's rules.

- Fix atomic operations for PPC when using IBM's XLC compiler (Noah Misch)
- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks` (Tom Lane)
- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Support building with Visual Studio 2015 (Michael Paquier, Petr Jelínek)

Note that builds made with VS2015 will not run on Windows versions before Windows Vista.

- Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)
- Avoid possibly-unsafe use of Windows' `FormatMessage()` function (Christian Ullrich)

Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

## E.42. Release 9.5.2

**Release date:** 2016-03-31

This release contains a variety of fixes from 9.5.1. For information about new features in the 9.5 major release, see Section E.44.

### E.42.1. Migration to Version 9.5.2

A dump/restore is not required for those running 9.5.X.

However, you may need to `REINDEX` some indexes after applying the update, as per the first changelog entry below.

### E.42.2. Changes

- Disable abbreviated keys for string sorting in non-C locales (Robert Haas)

PostgreSQL 9.5 introduced logic for speeding up comparisons of string data types by using the standard C library function `strxfrm()` as a substitute for `strcoll()`. It now emerges that most versions of `glibc` (Linux's implementation of the C library) have buggy implementations of `strxfrm()` that, in some locales, can produce string comparison results that do not match `strcoll()`. Until this problem can be better characterized, disable the optimization in all non-C locales. (C locale is safe since it uses neither `strcoll()` nor `strxfrm()`.)

Unfortunately, this problem affects not only sorting but also entry ordering in B-tree indexes, which means that B-tree indexes on `text`, `varchar`, or `char` columns may now be corrupt if they sort according to an affected locale and were built or modified under PostgreSQL 9.5.0 or 9.5.1. Users should `REINDEX` indexes that might be affected.

It is not possible at this time to give an exhaustive list of known-affected locales. C locale is known safe, and there is no evidence of trouble in English-based locales such as `en_US`, but some other popular locales such as `de_DE` are affected in most `glibc` versions.

- Maintain row-security status properly in cached plans (Stephen Frost)

In a session that performs queries as more than one role, the plan cache might incorrectly re-use a plan that was generated for another role ID, thus possibly applying the wrong set of policies when row-level security (RLS) is in use. (CVE-2016-2193)

- Add must-be-superuser checks to some new `contrib/pageinspect` functions (Andreas Seltenreich)

Most functions in the `pageinspect` extension that inspect `bytea` values disallow calls by non-superusers, but `brin_page_type()` and `brin_metapage_info()` failed to do so. Passing contrived `bytea` values to them might crash the server or disclose a few bytes of server memory. Add the missing permissions checks to prevent misuse. (CVE-2016-3065)

- Fix incorrect handling of indexed `ROW()` comparisons (Simon Riggs)

Flaws in a minor optimization introduced in 9.5 caused incorrect results if the `ROW()` comparison matches the index ordering partially but not exactly (for example, differing column order, or the index contains both `ASC` and `DESC` columns). Pending a better solution, the optimization has been removed.

- Fix incorrect handling of NULL index entries in indexed `ROW()` comparisons (Tom Lane)

An index search using a row comparison such as `ROW(a, b) > ROW('x', 'y')` would stop upon reaching a NULL entry in the `b` column, ignoring the fact that there might be non-NULL `b` values associated with later values of `a`.

- Avoid unlikely data-loss scenarios due to renaming files without adequate `fsync()` calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Fix incorrect behavior when rechecking a just-modified row in a query that does `SELECT FOR UPDATE/SHARE` and contains some relations that need not be locked (Tom Lane)

Rows from non-locked relations were incorrectly treated as containing all NULLs during the recheck, which could result in incorrectly deciding that the updated row no longer passes the `WHERE` condition, or in incorrectly outputting NULLs.

- Fix bug in `json_to_record()` when a field of its input object contains a sub-object with a field name matching one of the requested output column names (Tom Lane)
- Fix nonsense result from two-argument form of `jsonb_object()` when called with empty arrays (Michael Paquier, Andrew Dunstan)
- Fix misbehavior in `jsonb_set()` when converting a path array element into an integer for use as an array subscript (Michael Paquier)
- Fix misformatting of negative time zone offsets by `to_char()`'s `OF` format code (Thomas Munro, Tom Lane)
- Fix possible incorrect logging of waits done by `INSERT ... ON CONFLICT` (Peter Geoghegan)

Log messages would sometimes claim that the wait was due to an exclusion constraint although no such constraint was responsible.

- Ignore `recovery_min_apply_delay` parameter until recovery has reached a consistent state (Michael Paquier)

Previously, standby servers would delay application of WAL records in response to `recovery_min_apply_delay` even while replaying the initial portion of WAL needed to make their database state valid. Since the standby is useless until it's reached a consistent database state, this was deemed unhelpful.

- Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
- Fix assorted bugs in logical decoding (Andres Freund)

Trouble cases included tuples larger than one page when replica identity is `FULL`, `UPDATES` that change a primary key within a transaction large enough to be spooled to disk, incorrect reports of “subxact logged without previous toplevel record”, and incorrect reporting of a transaction's commit time.

- Fix planner error with nested security barrier views when the outer view has a `WHERE` clause containing a correlated subquery (Dean Rasheed)
- Fix memory leak in GIN index searches (Tom Lane)
- Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
- Fix parsing of affix files for `ispell` dictionaries (Tom Lane)

The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example `ı` in Turkish UTF8 locales.

- Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)

This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Fix atomic-operations code used on PPC with IBM's `xlc` compiler (Noah Misch)

This error led to rare failures of concurrent operations on that platform.

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)

This is a workaround for a bug in Visual Studio 2013's runtime library, which Microsoft have stated they will not fix in that version.

- Fix `psql`'s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)
- Fix `psql`'s tab completion for `SECURITY LABEL` (Tom Lane)

Pressing `TAB` after `SECURITY LABEL` might cause a crash or offering of inappropriate keywords.

- Make `pg_ctl` accept a wait timeout from the `PGCTLTIMEOUT` environment variable, if none is specified on the command line (Noah Misch)

This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

- Fix incorrect test for Windows service status in `pg_ctl` (Manuel Mathar)

The previous set of minor releases attempted to fix `pg_ctl` to properly determine whether to send log messages to Window's Event Log, but got the test backwards.

- Fix `pgbench` to correctly handle the combination of `-C` and `-M prepared` options (Tom Lane)
- In `pg_upgrade`, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)

Blind application of the script in such cases would result in loss of the new data directory.

- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren't valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by `contrib/pgstattuple`'s `pgstatindex()` function (Tom Lane)
- Remove dependency on `psed` in MSVC builds, since it's no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to `tzdata` release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

## E.43. Release 9.5.1

**Release date:** 2016-02-11

This release contains a variety of fixes from 9.5.0. For information about new features in the 9.5 major release, see Section E.44.

### E.43.1. Migration to Version 9.5.1

A dump/restore is not required for those running 9.5.X.

### E.43.2. Changes

- Fix infinite loops and buffer-overflow problems in regular expressions (Tom Lane)

Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- Fix an oversight that caused hash joins to miss joining to some tuples of the inner relation in rare cases (Tomas Vondra, Tom Lane)
- Avoid pushdown of `HAVING` clauses when grouping sets are used (Andrew Gierth)
- Fix deparsing of `ON CONFLICT` `arbitr` `WHERE` clauses (Peter Geoghegan)
- Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)

Previously, `%h/%r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)
- Fix `psql`'s `\det` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)
- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)
- Fix assorted corner-case bugs in `pg_dump`'s processing of extension member objects (Tom Lane)
- Fix improper quoting of domain constraint names in `pg_dump` (Elvis Pranskevichus)
- Make `pg_dump` mark a view's triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)
- Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)
- Suppress useless warning message when `pg_receivexlog` connects to a pre-9.4 server (Marco Nenciarini)
- Avoid dump/reload problems when using both `plpython2` and `plpython3` (Tom Lane)

In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of `libpython` cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

- Fix `ecpg`-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)

Such a comment is rejected by `ecpg`. It's not yet clear whether `ecpg` itself should be changed.

- Fix `hstore_to_json_loose()`'s test for whether an `hstore` value can be converted to a JSON number (Tom Lane)

Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.

- In `contrib/postgres_fdw`, fix bugs triggered by use of `tableoid` in data-modifying commands (Etsuro Fujita, Robert Haas)
- Fix ill-advised restriction of `NAMEDATALEN` to be less than 256 (Robert Haas, Tom Lane)
- Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)

This avoids possible bitwise differences in the produced executable files from one build to the next.

- Ensure that `dynloader.h` is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Update time zone data files to `tzdata` release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

## E.44. Release 9.5

**Release date:** 2016-01-07

## E.44.1. Overview

Major enhancements in PostgreSQL 9.5 include:

- Allow `INSERTS` that would generate constraint conflicts to be turned into `UPDATES` or ignored
- Add `GROUP BY` analysis features `GROUPING SETS`, `CUBE` and `ROLLUP`
- Add row-level security control
- Create mechanisms for tracking the progress of replication, including methods for identifying the origin of individual changes during logical replication
- Add Block Range Indexes (BRIN)
- Substantial performance improvements for sorting
- Substantial performance improvements for multi-CPU machines

The above items are explained in more detail in the sections below.

## E.44.2. Migration to Version 9.5

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.5 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Adjust operator precedence to match the SQL standard (Tom Lane)

The precedence of `<=`, `>=` and `<>` has been reduced to match that of `<`, `>` and `=`. The precedence of `IS` tests (e.g., `x IS NULL`) has been reduced to be just below these six comparison operators. Also, multi-keyword operators beginning with `NOT` now have the precedence of their base operator (for example, `NOT BETWEEN` now has the same precedence as `BETWEEN`) whereas before they had inconsistent precedence, behaving like `NOT` with respect to their left operand but like their base operator with respect to their right operand. The new configuration parameter `operator_precedence_warning` can be enabled to warn about queries in which these precedence changes result in different parsing choices.

- Change `pg_ctl`'s default shutdown mode from `smart` to `fast` (Bruce Momjian)

This means the default behavior will be to forcibly cancel existing database sessions, not simply wait for them to exit.

- Use assignment cast behavior for data type conversions in PL/pgSQL assignments, rather than converting to and from text (Tom Lane)

This change causes conversions of Booleans to strings to produce `true` or `false`, not `t` or `f`. Other type conversions may succeed in more cases than before; for example, assigning a numeric value `3.9` to an integer variable will now assign `4` rather than failing. If no assignment-grade cast is defined for the particular source and destination types, PL/pgSQL will fall back to its old I/O conversion behavior.

- Allow characters in server command-line options to be escaped with a backslash (Andres Freund)

Formerly, spaces in the options string always separated options, so there was no way to include a space in an option value. Including a backslash in an option value now requires writing `\\`.

- Change the default value of the GSSAPI `include_realm` parameter to `1`, so that by default the realm is not removed from a GSS or SSPI principal name (Stephen Frost)
- Replace configuration parameter `checkpoint_segments` with `min_wal_size` and `max_wal_size` (Heikki Linnakangas)

If you previously adjusted `checkpoint_segments`, the following formula will give you an approximately equivalent setting:

```
max_wal_size = (3 * checkpoint_segments) * 16MB
```

Note that the default setting for `max_wal_size` is much higher than the default `checkpoint_segments` used to be, so adjusting it might no longer be necessary.

- Control the Linux OOM killer via new environment variables `PG_OOM_ADJUST_FILE` and `PG_OOM_ADJUST_VALUE`, instead of compile-time options `LINUX_OOM_SCORE_ADJ` and `LINUX_OOM_ADJ` (Gurjeet Singh)
- Decommission server configuration parameter `ssl_renegotiation_limit`, which was deprecated in earlier releases (Andres Freund)

While SSL renegotiation is a good idea in theory, it has caused enough bugs to be considered a net negative in practice, and it is due to be removed from future versions of the relevant standards. We have therefore removed support for it from PostgreSQL. The `ssl_renegotiation_limit` parameter still exists, but cannot be set to anything but zero (disabled). It's not documented anymore, either.

- Remove server configuration parameter `autocommit`, which was already deprecated and non-operational (Tom Lane)
- Remove the `pg_authid` catalog's `rolcatupdate` field, as it had no usefulness (Adam Brightwell)
- The `pg_stat_replication` system view's `sent` field is now NULL, not zero, when it has no valid value (Magnus Hagander)
- Allow `json` and `jsonb` array extraction operators to accept negative subscripts, which count from the end of JSON arrays (Peter Geoghegan, Andrew Dunstan)

Previously, these operators returned NULL for negative subscripts.

### E.44.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.5 and the previous major release.

#### E.44.3.1. Server

##### E.44.3.1.1. Indexes

- Add Block Range Indexes (BRIN) (Álvaro Herrera)

BRIN indexes store only summary data (such as minimum and maximum values) for ranges of heap blocks. They are therefore very compact and cheap to update; but if the data is naturally clustered, they can still provide substantial speedup of searches.

- Allow queries to perform accurate distance filtering of bounding-box-indexed objects (polygons, circles) using GiST indexes (Alexander Korotkov, Heikki Linnakangas)

Previously, to exploit such an index a subquery had to be used to select a large number of rows ordered by bounding-box distance, and the result then had to be filtered further with a more accurate distance calculation.

- Allow GiST indexes to perform index-only scans (Anastasia Lubennikova, Heikki Linnakangas, Andreas Karlsson)
- Add configuration parameter `gin_pending_list_limit` to control the size of GIN pending lists (Fujii Masao)

This value can also be set on a per-index basis as an index storage parameter. Previously the pending-list size was controlled by `work_mem`, which was awkward because appropriate values for `work_mem` are often much too large for this purpose.

- Issue a warning during the creation of hash indexes because they are not crash-safe (Bruce Momjian)

#### **E.44.3.1.2. General Performance**

- Improve the speed of sorting of `varchar`, `text`, and `numeric` fields via “abbreviated” keys (Peter Geoghegan, Andrew Gierth, Robert Haas)
- Extend the infrastructure that allows sorting to be performed by inlined, non-SQL-callable comparison functions to cover `CREATE INDEX`, `REINDEX`, and `CLUSTER` (Peter Geoghegan)
- Improve performance of hash joins (Tomas Vondra, Robert Haas)
- Improve concurrency of shared buffer replacement (Robert Haas, Amit Kapila, Andres Freund)
- Reduce the number of page locks and pins during index scans (Kevin Grittner)

The primary benefit of this is to allow index vacuums to be blocked less often.

- Make per-backend tracking of buffer pins more memory-efficient (Andres Freund)
- Improve lock scalability (Andres Freund)

This particularly addresses scalability problems when running on systems with multiple CPU sockets.

- Allow the optimizer to remove unnecessary references to left-joined subqueries (David Rowley)
- Allow pushdown of query restrictions into subqueries with window functions, where appropriate (David Rowley)
- Allow a non-leakproof function to be pushed down into a security barrier view if the function does not receive any view output columns (Dean Rasheed)
- Teach the planner to use statistics obtained from an expression index on a boolean-returning function, when a matching function call appears in `WHERE` (Tom Lane)
- Make `ANALYZE` compute basic statistics (null fraction and average column width) even for columns whose data type lacks an equality function (Oleksandr Shulgin)
- Speed up CRC (cyclic redundancy check) computations and switch to CRC-32C (Abhijit Menon-Sen, Heikki Linnakangas)
- Improve bitmap index scan performance (Teodor Sigaev, Tom Lane)
- Speed up `CREATE INDEX` by avoiding unnecessary memory copies (Robert Haas)
- Increase the number of buffer mapping partitions (Amit Kapila, Andres Freund, Robert Haas)

This improves performance for highly concurrent workloads.

#### **E.44.3.1.3. Monitoring**

- Add per-table autovacuum logging control via new `log_autovacuum_min_duration` storage parameter (Michael Paquier)
- Add new configuration parameter `cluster_name` (Thomas Munro)

This string, typically set in `postgresql.conf`, allows clients to identify the cluster. This name also appears in the process title of all server processes, allowing for easier identification of processes belonging to the same cluster.

- Prevent non-superusers from changing `log_disconnections` on connection startup (Fujii Masao)

#### **E.44.3.1.4. SSL**

- Check “Subject Alternative Names” in SSL server certificates, if present (Alexey Klyukin)

When they are present, this replaces checks against the certificate's “Common Name”.

- Add system view `pg_stat_ssl` to report SSL connection information (Magnus Hagander)
- Add `libpq` functions to return SSL information in an implementation-independent way (Heikki Linnakangas)

While `PQgetssl()` can still be used to call OpenSSL functions, it is now considered deprecated because future versions of `libpq` might support other SSL implementations. When possible, use the new functions `PQsslAttribute()`, `PQsslAttributeNames()`, and `PQsslInUse()` to obtain SSL information in an SSL-implementation-independent way.

- Make `libpq` honor any OpenSSL thread callbacks (Jan Urbanski)

Previously they were overwritten.

#### E.44.3.1.5. Server Settings

- Replace configuration parameter `checkpoint_segments` with `min_wal_size` and `max_wal_size` (Heikki Linnakangas)

This change allows the allocation of a large number of WAL files without keeping them after they are no longer needed. Therefore the default for `max_wal_size` has been set to 1GB, much larger than the old default for `checkpoint_segments`. Also note that standby servers perform restartpoints to try to limit their WAL space consumption to `max_wal_size`; previously they did not pay any attention to `checkpoint_segments`.

- Control the Linux OOM killer via new environment variables `PG_OOM_ADJUST_FILE` and `PG_OOM_ADJUST_VALUE` (Gurjeet Singh)

The previous OOM control infrastructure involved compile-time options `LINUX_OOM_SCORE_ADJ` and `LINUX_OOM_ADJ`, which are no longer supported. The new behavior is available in all builds.

- Allow recording of transaction commit time stamps when configuration parameter `track_commit_timestamp` is enabled (Álvaro Herrera, Petr Jelinek)

Time stamp information can be accessed using functions `pg_xact_commit_timestamp()` and `pg_last_committed_xact()`.

- Allow `local_preload_libraries` to be set by `ALTER ROLE SET` (Peter Eisentraut, Kyotaro Horiguchi)
- Allow autovacuum workers to respond to configuration parameter changes during a run (Michael Paquier)
- Make configuration parameter `debug_assertions` read-only (Andres Freund)

This means that assertions can no longer be turned off if they were enabled at compile time, allowing for more efficient code optimization. This change also removes the `postgres -A` option.

- Allow setting `effective_io_concurrency` on systems where it has no effect (Peter Eisentraut)
- Add system view `pg_file_settings` to show the contents of the server's configuration files (Sawada Masahiko)
- Add `pending_restart` to the system view `pg_settings` to indicate a change has been made but will not take effect until a database restart (Peter Eisentraut)
- Allow `ALTER SYSTEM` values to be reset with `ALTER SYSTEM RESET` (Vik Fearing)

This command removes the specified setting from `postgresql.auto.conf`.

#### E.44.3.2. Replication and Recovery

- Create mechanisms for tracking the progress of replication, including methods for identifying the origin of individual changes during logical replication (Andres Freund)

This is helpful when implementing replication solutions.

- Rework truncation of the multixact commit log to be properly WAL-logged (Andres Freund)

This makes things substantially simpler and more robust.

- Add `recovery.conf` parameter `recovery_target_action` to control post-recovery activity (Petr Jelínek)

This replaces the old parameter `pause_at_recovery_target`.

- Add new `archive_mode` value `always` to allow standbys to always archive received WAL files (Fujii Masao)
- Add configuration parameter `wal_retrieve_retry_interval` to control WAL read retry after failure (Alexey Vasiliev, Michael Paquier)

This is particularly helpful for warm standbys.

- Allow compression of full-page images stored in WAL (Rahila Syed, Michael Paquier)

This feature reduces WAL volume, at the cost of more CPU time spent on WAL logging and WAL replay. It is controlled by a new configuration parameter `wal_compression`, which currently is off by default.

- Archive WAL files with suffix `.partial` during standby promotion (Heikki Linnakangas)
- Add configuration parameter `log_replication_commands` to log replication commands (Fujii Masao)

By default, replication commands, e.g. `IDENTIFY_SYSTEM`, are not logged, even when `log_statement` is set to `all`.

- Report the processes holding replication slots in `pg_replication_slots` (Craig Ringer)

The new output column is `active_pid`.

- Allow `recovery.conf`'s `primary_conninfo` setting to use connection URIs, e.g. `postgres://` (Alexander Shulgin)

### E.44.3.3. Queries

- Allow `INSERTS` that would generate constraint conflicts to be turned into `UPDATES` or ignored (Peter Geoghegan, Heikki Linnakangas, Andres Freund)

The syntax is `INSERT ... ON CONFLICT DO NOTHING/UPDATE`. This is the Postgres implementation of the popular `UPSERT` command.

- Add `GROUP BY` analysis features `GROUPING SETS`, `CUBE` and `ROLLUP` (Andrew Gierth, Atri Sharma)
- Allow setting multiple target columns in an `UPDATE` from the result of a single sub-`SELECT` (Tom Lane)

This is accomplished using the syntax `UPDATE tab SET (col1, col2, ...) = (SELECT ...)`.

- Add `SELECT` option `SKIP LOCKED` to skip locked rows (Thomas Munro)

This does not throw an error for locked rows like `NOWAIT` does.

- Add `SELECT` option `TABLESAMPLE` to return a subset of a table (Petr Jelínek)

This feature supports the SQL-standard table sampling methods. In addition, there are provisions for user-defined table sampling methods.

- Suggest possible matches for mistyped column names (Peter Geoghegan, Robert Haas)

### E.44.3.4. Utility Commands

- Add more details about sort ordering in `EXPLAIN` output (Marius Timmer, Lukas Kreft, Arne Schaffer)

Details include `COLLATE`, `DESC`, `USING`, and `NULLS FIRST/LAST`.

- Make `VACUUM` log the number of pages skipped due to pins (Jim Nasby)
- Make `TRUNCATE` properly update the `pg_stat*` tuple counters (Alexander Shulgin)
- Allow `REINDEX` to reindex an entire schema using the `SCHEMA` option (Sawada Masahiko)
- Add `VERBOSE` option to `REINDEX` (Sawada Masahiko)
- Prevent `REINDEX DATABASE` and `SCHEMA` from outputting object names, unless `VERBOSE` is used (Simon Riggs)
- Remove obsolete `FORCE` option from `REINDEX` (Fujii Masao)

### E.44.3.5. Object Manipulation

- Add row-level security control (Craig Ringer, KaiGai Kohei, Adam Brightwell, Dean Rasheed, Stephen Frost)

This feature allows row-by-row control over which users can add, modify, or even see rows in a table. This is controlled by new commands `CREATE/ALTER/DROP POLICY` and `ALTER TABLE ... ENABLE/DISABLE ROW SECURITY`.

- Allow changing of the WAL logging status of a table after creation with `ALTER TABLE ... SET LOGGED / UNLOGGED` (Fabrízio de Royes Mello)
- Add `IF NOT EXISTS` clause to `CREATE TABLE AS`, `CREATE INDEX`, `CREATE SEQUENCE`, and `CREATE MATERIALIZED VIEW` (Fabrízio de Royes Mello)
- Add support for `IF EXISTS` to `ALTER TABLE ... RENAME CONSTRAINT` (Bruce Momjian)
- Allow some DDL commands to accept `CURRENT_USER` or `SESSION_USER`, meaning the current user or session user, in place of a specific user name (Kyotaro Horiguchi, Álvaro Herrera)

This feature is now supported in `ALTER USER`, `ALTER GROUP`, `ALTER ROLE`, `GRANT`, and `ALTER object OWNER TO` commands.

- Support comments on domain constraints (Álvaro Herrera)
- Reduce lock levels of some create and alter trigger and foreign key commands (Simon Riggs, Andreas Karlsson)
- Allow `LOCK TABLE ... ROW EXCLUSIVE MODE` for those with `INSERT` privileges on the target table (Stephen Frost)

Previously this command required `UPDATE`, `DELETE`, or `TRUNCATE` privileges.

- Apply table and domain `CHECK` constraints in order by name (Tom Lane)

The previous ordering was indeterminate.

- Allow `CREATE/ALTER DATABASE` to manipulate `datistemplate` and `dataallowconn` (Vik Fearing)

This allows these per-database settings to be changed without manually modifying the `pg_database` system catalog.

#### E.44.3.5.1. Foreign Tables

- Add support for `IMPORT FOREIGN SCHEMA` (Ronan Dunklau, Michael Paquier, Tom Lane)

This command allows automatic creation of local foreign tables that match the structure of existing tables on a remote server.

- Allow `CHECK` constraints to be placed on foreign tables (Shigeru Hanada, Etsuro Fujita)

Such constraints are assumed to be enforced on the remote server, and are not enforced locally. However, they are assumed to hold for purposes of query optimization, such as constraint exclusion.

- Allow foreign tables to participate in inheritance (Shigeru Hanada, Etsuro Fujita)

To let this work naturally, foreign tables are now allowed to have check constraints marked as not valid, and to set storage and `OID` characteristics, even though these operations are effectively no-ops for a foreign table.

- Allow foreign data wrappers and custom scans to implement join pushdown (KaiGai Kohei)

#### **E.44.3.5.2. Event Triggers**

- Whenever a `ddl_command_end` event trigger is installed, capture details of DDL activity for it to inspect (Álvaro Herrera)

This information is available through a set-returning function `pg_event_trigger_ddl_commands()`, or by inspection of C data structures if that function doesn't provide enough detail.

- Allow event triggers on table rewrites caused by `ALTER TABLE` (Dimitri Fontaine)
- Add event trigger support for database-level `COMMENT`, `SECURITY LABEL`, and `GRANT/REVOKE` (Álvaro Herrera)
- Add columns to the output of `pg_event_trigger_dropped_objects` (Álvaro Herrera)

This allows simpler processing of delete operations.

#### **E.44.3.6. Data Types**

- Allow the `xml` data type to accept empty or all-whitespace content values (Peter Eisentraut)

This is required by the SQL/XML specification.

- Allow `macaddr` input using the format `xxxx-xxxx-xxxx` (Herwin Weststrate)
- Disallow non-SQL-standard syntax for `interval` with both precision and field specifications (Bruce Momjian)

Per the standard, such type specifications should be written as, for example, `INTERVAL MINUTE TO SECOND (2)`. PostgreSQL formerly allowed this to be written as `INTERVAL (2) MINUTE TO SECOND`, but it must now be written in the standard way.

- Add selectivity estimators for `inet/cidr` operators and improve estimators for text search functions (Emre Hasegeli, Tom Lane)
- Add data types `regrole` and `regnamespace` to simplify entering and pretty-printing the `OID` of a role or namespace (Kyotaro Horiguchi)

#### **E.44.3.6.1. JSON**

- Add `jsonb` functions `jsonb_set()` and `jsonb_pretty()` (Dmitry Dolgov, Andrew Dunstan, Petr Jelínek)
- Add `jsonb` generator functions `to_jsonb()`, `jsonb_object()`, `jsonb_build_object()`, `jsonb_build_array()`, `jsonb_agg()`, and `jsonb_object_agg()` (Andrew Dunstan)

Equivalent functions already existed for type `json`.

- Reduce casting requirements to/from `json` and `jsonb` (Tom Lane)
- Allow `text`, `text array`, and `integer` values to be subtracted from `jsonb` documents (Dmitry Dolgov, Andrew Dunstan)
- Add `jsonb ||` operator (Dmitry Dolgov, Andrew Dunstan)

- Add `json_strip_nulls()` and `jsonb_strip_nulls()` functions to remove JSON null values from documents (Andrew Dunstan)

### E.44.3.7. Functions

- Add `generate_series()` for numeric values (Plato Malugin)
- Allow `array_agg()` and `ARRAY()` to take arrays as inputs (Ali Akbar, Tom Lane)
- Add functions `array_position()` and `array_positions()` to return subscripts of array values (Pavel Stehule)
- Add a point-to-polygon distance operator `<->` (Alexander Korotkov)
- Allow multibyte characters as escapes in `SIMILAR TO` and `SUBSTRING` (Jeff Davis)

Previously, only a single-byte character was allowed as an escape.

- Add a `width_bucket()` variant that supports any sortable data type and non-uniform bucket widths (Petr Jelínek)
- Add an optional `missing_ok` argument to `pg_read_file()` and related functions (Michael Paquier, Heikki Linnakangas)
- Allow `=>` to specify named parameters in function calls (Pavel Stehule)

Previously only `:=` could be used. This requires removing the possibility for `=>` to be a user-defined operator. Creation of user-defined `=>` operators has been issuing warnings since PostgreSQL 9.0.

- Add POSIX-compliant rounding for platforms that use PostgreSQL-supplied rounding functions (Pedro Gimeno Fortea)

#### E.44.3.7.1. System Information Functions and Views

- Add function `pg_get_object_address()` to return OIDs that uniquely identify an object, and function `pg_identify_object_as_address()` to return object information based on OIDs (Álvaro Herrera)
- Loosen security checks for viewing queries in `pg_stat_activity`, executing `pg_cancel_backend()`, and executing `pg_terminate_backend()` (Stephen Frost)

Previously, only the specific role owning the target session could perform these operations; now membership in that role is sufficient.

- Add `pg_stat_get_snapshot_timestamp()` to output the time stamp of the statistics snapshot (Matt Kelly)

This represents the last time the snapshot file was written to the file system.

- Add `mxid_age()` to compute multi-xid age (Bruce Momjian)

#### E.44.3.7.2. Aggregates

- Add `min()/max()` aggregates for `inet/cidr` data types (Haribabu Kommi)
- Use 128-bit integers, where supported, as accumulators for some aggregate functions (Andreas Karlsson)

### E.44.3.8. Server-Side Languages

- Improve support for composite types in PL/Python (Ed Behn, Ronan Dunklau)

This allows PL/Python functions to return arrays of composite types.

- Reduce lossiness of PL/Python floating-point value conversions (Marko Kreen)
- Allow specification of conversion routines between SQL data types and data types of procedural languages (Peter Eisentraut)

This change adds new commands `CREATE/DROP TRANSFORM`. This also adds optional transformations between the `hstore` and `ltree` types to/from PL/Perl and PL/Python.

#### E.44.3.8.1. PL/pgSQL Server-Side Language

- Improve PL/pgSQL array performance (Tom Lane)
- Add an `ASSERT` statement in PL/pgSQL (Pavel Stehule)
- Allow more PL/pgSQL keywords to be used as identifiers (Tom Lane)

#### E.44.3.9. Client Applications

- Move `pg_archivecleanup`, `pg_test_fsync`, `pg_test_timing`, and `pg_xlogdump` from `contrib` to `src/bin` (Peter Eisentraut)

This should result in these programs being installed by default in most installations.

- Add `pg_rewind`, which allows re-synchronizing a master server after failback (Heikki Linnakangas)
- Allow `pg_receivexlog` to manage physical replication slots (Michael Paquier)

This is controlled via new `--create-slot` and `--drop-slot` options.

- Allow `pg_receivexlog` to synchronously flush WAL to storage using new `--synchronous` option (Furuya Osamu, Fujii Masao)

Without this, WAL files are `fsync`'ed only on close.

- Allow `vacuumdb` to vacuum in parallel using new `--jobs` option (Dilip Kumar)
- In `vacuumdb`, do not prompt for the same password repeatedly when multiple connections are necessary (Haribabu Kommi, Michael Paquier)
- Add `--verbose` option to `reindexdb` (Sawada Masahiko)
- Make `pg_basebackup` use a tablespace mapping file when using tar format, to support symbolic links and file paths of 100+ characters in length on MS Windows (Amit Kapila)
- Add `pg_xlogdump` option `--stats` to display summary statistics (Abhijit Menon-Sen)
- Allow `psql` to produce AsciiDoc output (Szymon Guz)
- Add an `errors` mode that displays only failed commands to `psql`'s `ECHO` variable (Pavel Stehule)

This behavior can also be selected with `psql`'s `-b` option.

- Provide separate column, header, and border linestyle control in `psql`'s unicode linestyle (Pavel Stehule)

Single or double lines are supported; the default is `single`.

- Add new option `%l` in `psql`'s `PROMPT` variables to display the current multiline statement line number (Sawada Masahiko)
- Add `\pset` option `pager_min_lines` to control pager invocation (Andrew Dunstan)
- Improve `psql` line counting used when deciding to invoke the pager (Andrew Dunstan)
- `psql` now fails if the file specified by an `--output` or `--log-file` switch cannot be written (Tom Lane, Daniel Vérité)

Previously, it effectively ignored the switch in such cases.

- Add `psql` tab completion when setting the `search_path` variable (Jeff Janes)

Currently only the first schema can be tab-completed.

- Improve `psql`'s tab completion for triggers and rules (Andreas Karlsson)

**1. Backslash Commands**

- Add `psql \? help` sections `variables` and `options` (Pavel Stehule)

`\? variables` shows `psql`'s special variables and `\? options` shows the command-line options. `\? commands` shows the meta-commands, which is the traditional output and remains the default. These help displays can also be obtained with the command-line option `--help=section`.

- Show tablespace size in `psql`'s `\db+` (Fabrízio de Royes Mello)
- Show data type owners in `psql`'s `\dT+` (Magnus Hagander)
- Allow `psql`'s `\watch` to output `\timing` information (Fujii Masao)

Also prevent `--echo-hidden` from echoing `\watch` queries, since that is generally unwanted.

- Make `psql`'s `\sf` and `\ef` commands honor `ECHO_HIDDEN` (Andrew Dunstan)
- Improve `psql` tab completion for `\set`, `\unset`, and `:variable` names (Pavel Stehule)
- Allow tab completion of role names in `psql \c` commands (Ian Barwick)

- Allow `pg_dump` to share a snapshot taken by another session using `--snapshot` (Simon Riggs, Michael Paquier)

The remote snapshot must have been exported by `pg_export_snapshot()` or logical replication slot creation. This can be used to share a consistent snapshot across multiple `pg_dump` processes.

- Support table sizes exceeding 8GB in tar archive format (Tom Lane)

The POSIX standard for tar format does not allow elements of a tar archive to exceed 8GB, but most modern implementations of tar support an extension that does allow it. Use the extension format when necessary, rather than failing.

- Make `pg_dump` always print the server and `pg_dump` versions (Jing Wang)

Previously, version information was only printed in `--verbose` mode.

- Remove the long-ignored `-i/--ignore-version` option from `pg_dump`, `pg_dumpall`, and `pg_restore` (Fujii Masao)
- Support multiple `pg_ctl -o` options, concatenating their values (Bruce Momjian)
- Allow control of `pg_ctl`'s event source logging on MS Windows (MauMau)

This only controls `pg_ctl`, not the server, which has separate settings in `postgresql.conf`.

- If the server's listen address is set to a wildcard value (`0.0.0.0` in IPv4 or `:::` in IPv6), connect via the loopback address rather than trying to use the wildcard address literally (Kondo Yuta)

This fix primarily affects Windows, since on other platforms `pg_ctl` will prefer to use a Unix-domain socket.

- Move `pg_upgrade` from `contrib` to `src/bin` (Peter Eisentraut)

In connection with this change, the functionality previously provided by the `pg_upgrade_support` module has been moved into the core server.

- Support multiple `pg_upgrade -o/-O` options, concatenating their values (Bruce Momjian)
- Improve database collation comparisons in `pg_upgrade` (Heikki Linnakangas)
- Remove support for upgrading from 8.3 clusters (Bruce Momjian)
- Move `pgbench` from `contrib` to `src/bin` (Peter Eisentraut)

- Fix calculation of TPS number “excluding connections establishing” (Tatsuo Ishii, Fabien Coelho)  
The overhead for connection establishment was miscalculated whenever the number of `pgbench` threads was less than the number of client connections. Although this is clearly a bug, we won't back-patch it into pre-9.5 branches since it makes TPS numbers not comparable to previous results.
- Allow counting of `pgbench` transactions that take over a specified amount of time (Fabien Coelho)  
This is controlled by a new `--latency-limit` option.
- Allow `pgbench` to generate Gaussian/exponential distributions using `\setrandom` (Kondo Mitsumasa, Fabien Coelho)
- Allow `pgbench`'s `\set` command to handle arithmetic expressions containing more than one operator, and add `%` (modulo) to the set of operators it supports (Robert Haas, Fabien Coelho)

### **E.44.3.10. Source Code**

- Simplify WAL record format (Heikki Linnakangas)  
This allows external tools to more easily track what blocks are modified.
- Improve the representation of transaction commit and abort WAL records (Andres Freund)
- Add atomic memory operations API (Andres Freund)
- Allow custom path and scan methods (KaiGai Kohei, Tom Lane)  
This allows extensions greater control over the optimizer and executor.
- Allow foreign data wrappers to do post-filter locking (Etsuro Fujita)
- Foreign tables can now take part in `INSERT ... ON CONFLICT DO NOTHING` queries (Peter Geoghegan, Heikki Linnakangas, Andres Freund)  
Foreign data wrappers must be modified to handle this. `INSERT ... ON CONFLICT DO UPDATE` is not supported on foreign tables.
- Improve `hash_create()`'s API for selecting simple-binary-key hash functions (Teodor Sigaev, Tom Lane)
- Improve parallel execution infrastructure (Robert Haas, Amit Kapila, Noah Misch, Rushabh Lathia, Jeevan Chalke)
- Remove Alpha (CPU) and Tru64 (OS) ports (Andres Freund)
- Remove swap-byte-based spinlock implementation for ARMv5 and earlier CPUs (Robert Haas)  
ARMv5's weak memory ordering made this locking implementation unsafe. Spinlock support is still possible on newer gcc implementations with atomics support.
- Generate an error when excessively long (100+ character) file paths are written to tar files (Peter Eisentraut)  
Tar does not support such overly-long paths.
- Change index operator class for columns `pg_seclabel.provider` and `pg_shseclabel.provider` to be `text_pattern_ops` (Tom Lane)  
This avoids possible problems with these indexes when different databases of a cluster have different default collations.
- Change the spinlock primitives to function as compiler barriers (Robert Haas)

#### **E.44.3.10.1. MS Windows**

- Allow higher-precision time stamp resolution on Windows 8, Windows Server 2012, and later Windows systems (Craig Ringer)

- Install shared libraries to `bin` in MS Windows (Peter Eisentraut, Michael Paquier)
- Install `src/test/modules` together with `contrib` on MSVC builds (Michael Paquier)
- Allow `configure`'s `--with-extra-version` option to be honored by the MSVC build (Michael Paquier)
- Pass `PGFILEDESC` into MSVC `contrib` builds (Michael Paquier)
- Add icons to all MSVC-built binaries and version information to all MS Windows binaries (Noah Misch)

MinGW already had such icons.

- Add optional-argument support to the internal `getopt_long()` implementation (Michael Paquier, Andres Freund)

This is used by the MSVC build.

### E.44.3.11. Additional Modules

- Add statistics for minimum, maximum, mean, and standard deviation times to `pg_stat_statements` (Mitsumasa Kondo, Andrew Dunstan)
- Add `pgcrypto` function `pgp_armor_headers()` to extract PGP armor headers (Marko Tiikkaja, Heikki Linnakangas)
- Allow empty replacement strings in `unaccent` (Mohammad Alhashash)

This is useful in languages where diacritic signs are represented as separate characters.

- Allow multicharacter source strings in `unaccent` (Tom Lane)

This could be useful in languages where diacritic signs are represented as separate characters. It also allows more complex `unaccent` dictionaries.

- Add `contrib` modules `tsm_system_rows` and `tsm_system_time` to allow additional table sampling methods (Petr Jelínek)
- Add GIN index inspection functions to `pageinspect` (Heikki Linnakangas, Peter Geoghegan, Michael Paquier)
- Add information about buffer pins to `pg_buffercache` display (Andres Freund)
- Allow `pgstattuple` to report approximate answers with less overhead using `pgstattuple_approx()` (Abhijit Menon-Sen)
- Move `dummy_seclabel`, `test_shm_mq`, `test_parser`, and `worker_spi` from `contrib` to `src/test/modules` (Álvaro Herrera)

These modules are only meant for server testing, so they do not need to be built or installed when packaging PostgreSQL.

## E.45. Release 9.4.15

**Release date:** 2017-11-09

This release contains a variety of fixes from 9.4.14. For information about new features in the 9.4 major release, see Section E.60.

### E.45.1. Migration to Version 9.4.15

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.47.

## E.45.2. Changes

- Fix crash due to rowtype mismatch in `json{b}_populate_recordset()` (Michael Paquier, Tom Lane)

These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn't, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)
- Fix `json_build_array()`, `json_build_object()`, and their `jsonb` equivalents to handle explicit `VARIADIC` arguments correctly (Michael Paquier)
- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range's subtype has hash support. This does not affect any of the built-in range types, since they're all hashable anyway.

- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid `SIGBUS` crash on Linux when a DSM memory request exceeds the space available in `tmpfs` (Thomas Munro)
- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Allow `COPY`'s `FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)

This case was unintentionally broken by a previous bug fix.

- Correctly restore the `umask` setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)
- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)
- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)

- Fix libpq to not require user's home directory to exist (Tom Lane)

In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- Fix libpq to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)
- Fix ecpg's handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
- In ecpglib, correctly handle backslashes in string literals depending on whether `standard_conforming_strings` is set (Tsunakawa Takayuki)
- Make ecpglib's Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Sync our copy of the timezone library with IANA release `tzcode2017c` (Tom Lane)

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to `tzdata` release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

## E.46. Release 9.4.14

**Release date:** 2017-08-31

This release contains a small number of fixes from 9.4.13. For information about new features in the 9.4 major release, see Section E.60.

### E.46.1. Migration to Version 9.4.14

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.13, see Section E.47.

### E.46.2. Changes

- Fix failure of walsender processes to respond to shutdown signals (Marco Nenciarini)

A missed flag update resulted in walsenders continuing to run as long as they had a standby server connected, preventing primary-server shutdown unless immediate shutdown mode is used.

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in `psql`:

```
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
    SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
           CAST(grantee.rolname AS sql_identifier) AS grantee,
           CAST(current_database() AS sql_identifier) AS table_catalog,
           CAST(nc.nspname AS sql_identifier) AS table_schema,
           CAST(c.relname AS sql_identifier) AS table_name,
           CAST(c.prtype AS character_data) AS privilege_type,
           CAST(
```

```

CASE WHEN
    -- object owner always has grant options
    pg_has_role(grantee.oid, c.relower, 'USAGE')
    OR c.grantable
    THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no)
AS with_hierarchy

FROM (
    SELECT oid, relname, relnamespace, relkind, relower,
(aclexplode(coalesce(relacl, acldefault('r', relower)))).* FROM pg_class
) AS c (oid, relname, relnamespace, relkind, relower, grantor, grantee,
prtype, grantable),
pg_namespace nc,
pg_authid u_grantor,
(
    SELECT oid, rolname FROM pg_authid
    UNION ALL
    SELECT 0::oid, 'PUBLIC'
) AS grantee (oid, rolname)

WHERE c.relnamespace = nc.oid
AND c.relkind IN ('r', 'v', 'f')
AND c.grantee = grantee.oid
AND c.grantor = u_grantor.oid
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE',
'REFERENCES', 'TRIGGER')
AND (pg_has_role(u_grantor.oid, 'USAGE')
OR pg_has_role(grantee.oid, 'USAGE')
OR grantee.rolname = 'PUBLIC');

```

This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)

This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Fix crash in `pg_restore` when using parallel mode and using a list file to select a subset of items to restore (Fabrício de Royes Mello)
- Change `ecpg`'s parser to allow RETURNING clauses without attached C variables (Michael Meskes)

This allows `ecpg` programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T`

is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.

## E.47. Release 9.4.13

**Release date:** 2017-08-10

This release contains a variety of fixes from 9.4.12. For information about new features in the 9.4 major release, see Section E.60.

### E.47.1. Migration to Version 9.4.13

A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.12, see Section E.48.

### E.47.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you'll still need a restart.)
2. In *each* database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;
CREATE OR REPLACE VIEW pg_user_mappings AS
  SELECT
    U.oid      AS umid,
    S.oid      AS srvid,
    S.srvname  AS srvname,
    U.umuser   AS umuser,
    CASE WHEN U.umuser = 0 THEN
      'public'
    ELSE
      A.rolname
    END AS username,
    CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
              AND (pg_has_role(S.srvowner, 'USAGE')
                   OR has_server_privilege(S.oid, 'USAGE')))
      OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
      OR (SELECT rolsuper FROM pg_authid WHERE rolname =
current_user)
    THEN U.umoptions
    ELSE NULL END AS umoptions
  FROM pg_user_mapping U
  LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
```

```
pg_foreign_server S ON (U.umserver = S.oid);
```

3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing `template0`, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';  
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.
- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)  
  
libpq ignores empty password specifications, and does not transmit them to the server. So, if a user's password has been set to the empty string, it's impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, `md5`, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)
  - Make `lo_put()` check for `UPDATE` privilege on the target large object (Tom Lane, Michael Paquier)  
  
`lo_put()` should surely require the same permissions as `lowrite()`, but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)
  - Fix concurrent locking of tuple update chains (Álvaro Herrera)  
  
If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.
  - Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)
  - Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Kopysov)
  - On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)  
  
This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.
  - Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
  - Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
  - Prevent sending SSL session tickets to clients (Tom Lane)

This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting `tcp_keepalives_idle` on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector's receive buffer size is at least 100KB (Tom Lane)

This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an `XLOG_SWITCH` WAL record (Andres Freund)
- Fix walsender to exit promptly when client requests shutdown (Tom Lane)
- Fix `SIGHUP` and `SIGUSR1` handling in walsender processes (Petr Jelinek, Andres Freund)
- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix logical decoding failure with very wide tuples (Andres Freund)

Logical decoding crashed on tuples that are wider than 64KB (after compression, but with all data in-line). The case arises only when `REPLICA IDENTITY FULL` is enabled for a table containing such tuples.

- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)

This resulted in temporary files consuming excessive disk space.

- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)

The previous algorithm was infeasibly expensive on a server with a lot of open transactions.

- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)
- Reduce overhead in processing syscache invalidation events (Tom Lane)

This is particularly helpful for logical decoding, which triggers frequent cache invalidation.

- Fix cases where an `INSERT` or `UPDATE` assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Allow window functions to be used in sub-`SELECTS` that are within the arguments of an aggregate function (Tom Lane)
- Move autogenerated array types out of the way during `ALTER ... RENAME` (Vik Fearing)

Previously, we would rename a conflicting autogenerated array type out of the way during `CREATE`; this fix extends that behavior to renaming operations.

- Ensure that `ALTER USER ... SET` accepts all the syntax variants that `ALTER ROLE ... SET` does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function's argument or return type from `opaque` to the correct type (Heikki Linnakangas)

`CREATE TYPE` updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent `DROP TYPE` to leave broken function definitions behind.

- Reduce memory usage when `ANALYZE` processes a `tsvector` column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing `money` values by integers or floats (Tom Lane)

- Tighten checks for whitespace in functions that parse identifiers, such as `regprocedurein()` (Tom Lane)

Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant `#define` symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In `libpq`, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In `psql`, fix failure when `COPY FROM STDIN` is ended with a keyboard EOF signal and then another `COPY FROM STDIN` is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix `pg_dump` and `pg_restore` to emit `REFRESH MATERIALIZED VIEW` commands last (Tom Lane)

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Improve `pg_dump/pg_restore`'s reporting of error conditions originating in `zlib` (Vladimir Kunschikov, Álvaro Herrera)

- Fix `pg_dump` with the `--clean` option to drop event triggers as expected (Tom Lane)

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix `pg_dump` to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

- Fix `pg_dump` output to `stdout` on Windows (Kuntal Ghosh)

A compressed plain-text dump written to `stdout` would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a `NATURAL LEFT JOIN` with no common columns (Tom Lane)

- Fix dumping of function expressions in the `FROM` clause in cases where the expression does not de-parse into something that looks like a function call (Tom Lane)

- Fix `pg_basebackup` output to `stdout` on Windows (Haribabu Kommi)

A backup written to `stdout` would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

- In `postgres_fdw`, re-establish connections to remote servers after `ALTER SERVER` or `ALTER USER MAPPING` commands (Kyotaro Horiguchi)

This ensures that option changes affecting connection parameters will be applied promptly.

- In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)

This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Increase `MAX_SYSCACHE_CALLBACKS` to provide more room for extensions (Tom Lane)
- Always use `-fPIC`, not `-fpic`, when building shared libraries with `gcc` (Tom Lane)

This supports larger extension libraries on platforms where it makes a difference.

- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the `openssl` library is not within a `VC` subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for `libxml2` header files (Andrew Dunstan)

This fixes a former need to move things around in standard Windows installations of `libxml2`.

- In MSVC builds, recognize a Tcl library that is named `tc186.lib` (Noah Misch)
- In MSVC builds, honor `PROVE_FLAGS` settings on `vc regress.pl`'s command line (Andrew Dunstan)

## E.48. Release 9.4.12

**Release date:** 2017-05-11

This release contains a variety of fixes from 9.4.11. For information about new features in the 9.4 major release, see Section E.60.

### E.48.1. Migration to Version 9.4.12

A dump/restore is not required for those running 9.4.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.11, see Section E.49.

### E.48.2. Changes

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.47.

- Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator's implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

- Restore libpq's recognition of the `PGREQUIRESSL` environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than `PGSSLMODE`, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

- Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)

The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

- Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

- Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Avoid possible crash in walsender due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)
- Fix postmaster's handling of `fork()` failure for a background worker process (Tom Lane)

Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
- Fix integer-overflow problems in `interval` comparison (Kyotaro Horiguchi, Tom Lane)

The comparison operators for type `interval` could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

- Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

- Fix roundoff problems in `float8_timestampz()` and `make_interval()` (Tom Lane)

These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)
- Reduce memory management overhead for contexts containing many large blocks (Tom Lane)
- Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn't accessible, so that no logging happens at all.

- Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)
- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`'s purposes.

- Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)

Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in `contrib/adminpack`'s `pg_file_write()` function (Noah Misch)

Notably, it failed to detect errors reported by `fclose()`.

- In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix `contrib/pg_trgm`'s extraction of trigrams from regular expressions (Tom Lane)

In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In `contrib/postgres_fdw`, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)

Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.

- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)

This is a back-patch of work previously done in newer branches; it's needed since many platforms are adopting newer OpenSSL versions.

- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release `tzcode2017b` (Tom Lane)

This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to `tzdata` release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the `posixrules` file in the `timezone` directory tree. This resulted in the `timezone` code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the `US/Eastern` zone. If you don't want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

## E.49. Release 9.4.11

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.4.10. For information about new features in the 9.4 major release, see Section E.60.

### E.49.1. Migration to Version 9.4.11

A dump/restore is not required for those running 9.4.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.4.10, see Section E.50.

## E.49.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)

Backends failed to account for this snapshot when advertising their oldest `xmin`, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

Previously, this was skipped when `wal_level = minimal`, but actually it's necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

This change avoids substantial replication delays that sometimes occurred while replaying such operations.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)
- Ensure that hot standby feedback works correctly when it's enabled at standby server start (Ants Aasma, Craig Ringer)
- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)
- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint's deferrability properties with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)

This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

This avoids “could not find trigger *NNN*” or “relation *NNN* has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)

The OID column should be treated the same as regular user columns in this case, but it wasn't, leading to odd behavior in later inheritance changes.

- Fix `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)

Previously the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)

The wrong catalog OID was reported to extensions such as logical decoding.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)

This led to "UPDATE target count mismatch --- internal error". Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)

This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don't share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)

Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)

- Fix `ts_rewrite()`'s handling of nested NOT operators (Tom Lane)

- Fix `array_fill()` to handle empty arrays properly (Tom Lane)

- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)

The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)

This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Avoid discarding `interval-to-interval` casts that aren't really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)
- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix `pg_restore` with `--create --if-exists` to behave more sanely if an archive contains unrecognized `DROP` commands (Tom Lane)

This doesn't fix any live bug, but it may improve the behavior in future if `pg_restore` is used with an archive generated by a later `pg_dump` version.

- Fix `pg_basebackup`'s rate limiting in the presence of slow I/O (Antonin Houska)

If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

- Fix `pg_basebackup`'s handling of symlinked `pg_stat_tmp` and `pg_replslot` subdirectories (Magnus Hagander, Michael Paquier)
- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)

This matches the (previously undocumented) behavior of PL/Tcl's `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn't a real column named that.

- Allow DOS-style line endings in `~/.pgpass` files, even on Unix (Vik Fearing)

This change simplifies use of the same password file across Unix and Windows machines.

- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix `psql`'s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)

Previously, such a setting caused output intended for the pager to vanish entirely.

- Improve `contrib/dblink`'s reporting of low-level `libpq` errors, such as out-of-memory (Joe Conway)
- Teach `contrib/dblink` to ignore irrelevant server options when it uses a `contrib/postgres_fdw` foreign server as the source of connection options (Corey Huinker)

Previously, if the foreign server object had options that were not also `libpq` connection options, an error occurred.

- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release `tzcode2016j` (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn't support hard links.

- Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

## E.50. Release 9.4.10

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.4.9. For information about new features in the 9.4 major release, see Section E.60.

### E.50.1. Migration to Version 9.4.10

A dump/restore is not required for those running 9.4.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.4.6, see Section E.54.

### E.50.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block xxx: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at [https://wiki.postgresql.org/wiki/Free\\_Space\\_Map\\_Problems](https://wiki.postgresql.org/wiki/Free_Space_Map_Problems).

- Fix incorrect creation of GIN index WAL records on big-endian machines (Tom Lane)

The typical symptom was “unexpected GIN leaf action” errors during WAL replay.

- Fix `SELECT FOR UPDATE/SHARE` to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)

In 9.5 and later, the `SELECT` would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gieth)

The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix query-lifespan memory leak in a bulk `UPDATE` on a table with a `PRIMARY KEY` or `REPLICA IDENTITY` index (Tom Lane)
- Fix `EXPLAIN` to emit valid XML when `track_io_timing` is on (Markus Winand)

Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- Suppress printing of zeroes for unmeasured times in `EXPLAIN` (Maksim Milyutin)

Certain option combinations resulted in printing zero values for times that actually aren't ever measured in that combination. Our general policy in `EXPLAIN` is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when `VACUUM` is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing `VACUUM` to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- Remove artificial restrictions on the values accepted by `numeric_in()` and `numeric_recv()` (Tom Lane)

We allow numeric values up to the limit of the storage format (more than  $1e100000$ ), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Fix logical WAL decoding to work properly when a subtransaction's WAL output is large enough to spill to disk (Andres Freund)
- Fix buffer overread in logical WAL decoding (Tom Lane)

Logical decoding of a tuple update record read 23 bytes too many, which was usually harmless but with very bad luck could result in a crash.

- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
- Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)

This can't do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn't designed with this situation in mind.

- Properly initialize replication slot state when recycling a previously-used slot (Michael Paquier)

This failure to reset all of the fields of the slot could prevent `VACUUM` from removing dead tuples.

- Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)

This avoids possible failures during `munmap()` on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.

- Use a more random value for the dynamic shared memory control segment's ID (Robert Haas, Tom Lane)

Previously, the same value would be chosen every time, because it was derived from `random()` but `srandom()` had not yet been called. While relatively harmless, this was not the intended behavior.

- On Windows, retry creation of the dynamic shared memory control segment after an access-denied error (Kyotaro Horiguchi, Amit Kapila)

Windows sometimes returns `ERROR_ACCESS_DENIED` rather than `ERROR_ALREADY_EXISTS` when there is an existing segment. This led to postmaster startup failure due to believing that the former was an unrecoverable error.

- Don't try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

- Make `ecpg's --help` and `--version` options work consistently with our other executables (Haribabu Kommi)
- Fix `pgbench's` calculation of average latency (Fabien Coelho)

The calculation was incorrect when there were `\sleep` commands in the script, or when the test duration was specified in number of transactions rather than total time.

- In `pg_dump`, never dump range constructor functions (Tom Lane)

This oversight led to `pg_upgrade` failures with extensions containing range types, due to duplicate creation of the constructor functions.

- In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Haggander)

This allows for a possible delay in the server's creation of the next segment.

- Fix `pg_xlogdump` to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
- Fix `contrib/pg_buffercache` to work when `shared_buffers` exceeds 256GB (KaiGai Kohei)
- Fix `contrib/intarray/bench/bench.pl` to print the results of the `EXPLAIN` it does when given the `-e` option (Daniel Gustafsson)
- Install TAP test infrastructure so that it's available for extension testing (Craig Ringer)

When PostgreSQL has been configured with `--enable-tap-tests`, "make install" will now install the Perl support files for TAP testing where PGXS can find them. This allows non-core extensions to use `$(prove_check)` without extra tests.

- In MSVC builds, include `pg_recvlogical` in a client-only installation (MauMau)
- Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in `tzdata` release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbrevs` view to fail altogether.

- Update time zone data files to `tzdata` release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, `AMT` is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the `Default` abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

## E.51. Release 9.4.9

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.4.8. For information about new features in the 9.4 major release, see Section E.60.

### E.51.1. Migration to Version 9.4.9

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.54.

### E.51.2. Changes

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function's body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs' handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in `vacuumdb` and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a `conninfo` string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in `psql`'s `\connect` and `\password` commands to match the documentation.

Introduce a new `-reuse-previous` option in `psql`'s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a `conninfo` string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

`pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that `IS NULL` should return `TRUE` for a row of all null values (thus `ROW(NULL, NULL) IS NULL` yields `TRUE`), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL, NULL)) IS NULL` yields `FALSE`). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing `TRUE` in both cases), and `contrib/postgres_fdw` could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

- Prevent crash in `close_ps()` (the `point ## lseg` operator) for NaN input coordinates (Tom Lane)

Make it return NULL instead of crashing.

- Avoid possible crash in `pg_get_expr()` when inconsistent values are passed to it (Michael Paquier, Thomas Munro)

- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)

This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn't exist yet.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Fix hint bit update during WAL replay of row locking operations (Andres Freund)

The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)

- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)

- Fix possible loss of large subtransactions in logical decoding (Petru-Florin Mihancea)

- Fix failure of logical decoding when a subtransaction contains no actual changes (Marko Tiikkaja, Andrew Gierth)

- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)

The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)

- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

Some cases in `VACUUM` unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during `VACUUM FREEZE` (Simon Riggs, Álvaro Herrera)

`VACUUM FREEZE` on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- Prevent possible failure when vacuuming multixact IDs in an installation that has been `pg_upgrade'd` from pre-9.3 (Andrew Gierth, Álvaro Herrera)

The usual symptom of this bug is errors like “MultiXactId *NNN* has not been created yet -- apparent wraparound”.

- When a manual `ANALYZE` specifies a column list, don't reset the table's `changes_since_analyze` counter (Tom Lane)

If we're only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix `ANALYZE`'s overestimation of `n_distinct` for a unique or nearly-unique column with many null entries (Tom Lane)

The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

Normally this isn't much of a problem because the vacuum doesn't take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Avoid duplicate buffer lock release when abandoning a b-tree index page deletion attempt (Tom Lane)

This mistake prevented `VACUUM` from completing in some cases involving corrupt b-tree indexes.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
- Fix `contrib/btree_gin` to handle the smallest possible `bigint` value correctly (Peter Eisentraut)
- Teach `libpq` to correctly decode server version from future servers (Peter Eisentraut)

It's planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that `PQserverVersion()` returns the correct value for such cases.

- Fix `ecpg`'s code for `unsigned long long` array elements (Michael Meskes)
- In `pg_dump` with both `-c` and `-C` options, avoid emitting an unwanted `CREATE SCHEMA public` command (David Johnston, Tom Lane)
- Improve handling of SIGTERM/control-C in parallel `pg_dump` and `pg_restore` (Tom Lane)

Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a `CREATE INDEX`.

- Fix error reporting in parallel `pg_dump` and `pg_restore` (Tom Lane)

Previously, errors reported by `pg_dump` or `pg_restore` worker processes might never make it to the user's console, because the messages went through the master process, and there were various deadlock scenarios that would prevent the master process from passing on the messages. Instead, just print everything to `stderr`. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.

- Ensure that parallel `pg_dump` or `pg_restore` on Windows will shut down properly after an error (Kyotaro Horiguchi)

Previously, it would report the error, but then just sit until manually stopped by the user.

- Make `pg_dump` behave better when built without `zlib` support (Kyotaro Horiguchi)

It didn't work right for parallel dumps, and emitted some rather pointless warnings in other cases.

- Make `pg_basebackup` accept `-Z 0` as specifying no compression (Fujii Masao)

- Fix makefiles' rule for building AIX shared libraries to be safe for parallel make (Noah Misch)
- Fix TAP tests and MSVC scripts to work when build directory's path name contains spaces (Michael Paquier, Kyotaro Horiguchi)
- Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)

On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.

- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA's tzcode release 2016c (Tom Lane)

This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

## E.52. Release 9.4.8

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.4.7. For information about new features in the 9.4 major release, see Section E.60.

### E.52.1. Migration to Version 9.4.8

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.54.

### E.52.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it's clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It's possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any *N*-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)
- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

Given a three-or-more-way equivalence class of variables, such as  $X.X = Y.Y = Z.Z$ , it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn't satisfy the `WHERE` clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix query-lifespan memory leak in GIN index scans (Julien Rouhaud)
- Fix query-lifespan memory leak and potential index corruption hazard in GIN index insertion (Tom Lane)

The memory leak would typically not amount to much in simple queries, but it could be very substantial during a large GIN index build with high `maintenance_work_mem`.

- Fix possible misbehavior of `TH`, `th`, and `Y,YYY` format codes in `to_timestamp()` (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the `array` argument of a `value operator ANY (array)` construct is a sub-SELECT (Tom Lane)
- Disallow newlines in `ALTER SYSTEM` parameter values (Tom Lane)

The configuration-file parser doesn't support embedded newlines in string literals, so we mustn't allow them in values to be inserted by `ALTER SYSTEM`.

- Fix `ALTER TABLE ... REPLICA IDENTITY USING INDEX` to work properly if an index on OID is selected (David Rowley)
- Fix crash in logical decoding on alignment-picky platforms (Tom Lane, Andres Freund)

The failure occurred only with a transaction large enough to spill to disk and a primary-key change within that transaction.

- Avoid repeated requests for feedback from receiver while shutting down walsender (Nick Cleaton)
- Make `pg_regress` use a startup timeout from the `PGCTLTIMEOUT` environment variable, if that's set (Tom Lane)

This is for consistency with a behavior recently added to `pg_ctl`; it eases automated testing on slow machines.

- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.

- Fix `pg_upgrade` to not fail when new-cluster TOAST rules differ from old (Tom Lane)

`pg_upgrade` had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can't get along fine without a TOAST table if that was okay according to the old version's rules.

- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks` (Tom Lane)
- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)
- Avoid possibly-unsafe use of Windows' `FormatMessage()` function (Christian Ullrich)

Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

## E.53. Release 9.4.7

**Release date:** 2016-03-31

This release contains a variety of fixes from 9.4.6. For information about new features in the 9.4 major release, see Section E.60.

### E.53.1. Migration to Version 9.4.7

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.6, see Section E.54.

### E.53.2. Changes

- Fix incorrect handling of NULL index entries in indexed `ROW()` comparisons (Tom Lane)

An index search using a row comparison such as `ROW(a, b) > ROW('x', 'y')` would stop upon reaching a NULL entry in the `b` column, ignoring the fact that there might be non-NULL `b` values associated with later values of `a`.

- Avoid unlikely data-loss scenarios due to renaming files without adequate `fsync()` calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)
- Fix bug in `json_to_record()` when a field of its input object contains a sub-object with a field name matching one of the requested output column names (Tom Lane)
- Fix misformatting of negative time zone offsets by `to_char()`'s `OF` format code (Thomas Munro, Tom Lane)
- Ignore `recovery_min_apply_delay` parameter until recovery has reached a consistent state (Michael Paquier)

Previously, standby servers would delay application of WAL records in response to `recovery_min_apply_delay` even while replaying the initial portion of WAL needed to make their database state valid. Since the standby is useless until it's reached a consistent database state, this was deemed unhelpful.

- Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
- Fix assorted bugs in logical decoding (Andres Freund)

Trouble cases included tuples larger than one page when replica identity is `FULL`, `UPDATES` that change a primary key within a transaction large enough to be spooled to disk, incorrect reports of “subxact logged without previous toplevel record”, and incorrect reporting of a transaction's commit time.

- Fix planner error with nested security barrier views when the outer view has a `WHERE` clause containing a correlated subquery (Dean Rasheed)
- Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
- Fix parsing of affix files for `ispell` dictionaries (Tom Lane)

The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example `İ` in Turkish UTF8 locales.

- Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)

This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)

This is a workaround for a bug in Visual Studio 2013's runtime library, which Microsoft have stated they will not fix in that version.

- Fix `psql`'s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)

- Fix `psql`'s tab completion for `SECURITY LABEL` (Tom Lane)

Pressing `TAB` after `SECURITY LABEL` might cause a crash or offering of inappropriate keywords.

- Make `pg_ctl` accept a wait timeout from the `PGCTLTIMEOUT` environment variable, if none is specified on the command line (Noah Misch)

This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

- Fix incorrect test for Windows service status in `pg_ctl` (Manuel Mathar)

The previous set of minor releases attempted to fix `pg_ctl` to properly determine whether to send log messages to Window's Event Log, but got the test backwards.

- Fix `pgbench` to correctly handle the combination of `-C` and `-M prepared` options (Tom Lane)
- In `pg_upgrade`, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)

Blind application of the script in such cases would result in loss of the new data directory.

- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren't valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by `contrib/pgstattuple`'s `pgstatindex()` function (Tom Lane)
- Remove dependency on `psed` in MSVC builds, since it's no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to `tzdata` release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

## E.54. Release 9.4.6

**Release date:** 2016-02-11

This release contains a variety of fixes from 9.4.5. For information about new features in the 9.4 major release, see Section E.60.

### E.54.1. Migration to Version 9.4.6

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading an installation that contains any GIN indexes that use the (non-default) `jsonb_path_ops` operator class, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.4, see Section E.56.

### E.54.2. Changes

- Fix inconsistent hash calculations in `jsonb_path_ops` GIN indexes (Tom Lane)

When processing `jsonb` values that contain both scalars and sub-objects at the same nesting level, for example an array containing both scalars and sub-arrays, key hash values could be calculated differently than they would be for the same key in a different context. This could result in queries not finding entries that they should find. Fixing this means that existing indexes may now be inconsistent with the new hash calculation code. Users should `REINDEX jsonb_path_ops` GIN indexes after installing this update to make sure that all searches work as expected.

- Fix infinite loops and buffer-overflow problems in regular expressions (Tom Lane)

Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- Perform an immediate shutdown if the `postmaster.pid` file is removed (Tom Lane)

The postmaster now checks every minute or so that `postmaster.pid` is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes `postmaster.pid` and then starts a new postmaster.

- In `SERIALIZABLE` transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)
- Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)

Even though the relation's data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)
- Ensure walsender slots are fully re-initialized when being re-used (Magnus Hagander)
- Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)
- Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)
- Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)
- Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)
- Fix possible crash after doing query rewrite for an updatable view (Stephen Frost)
- Fix planner's handling of `LATERAL` references (Tom Lane)

This fixes some corner cases that led to “failed to build any N-way joins” or “could not devise a query plan” planner failures.

- Add more defenses against bad planner cost estimates for GIN index scans when the index's internal statistics are very out-of-date (Tom Lane)
- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
- Speed up generation of unique table aliases in `EXPLAIN` and rule dumping, and ensure that generated aliases do not exceed `NAMEDATALEN` (Tom Lane)
- Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)
- Translation of minus-infinity dates and timestamps to `json` or `jsonb` incorrectly rendered them as plus-infinity (Tom Lane)
- Fix possible internal overflow in `numeric` division (Dean Rasheed)
- Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)

Lookahead constraints aren't allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

- Conversion of regular expressions to `indexscan` bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)
- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)

The code added for CVE-2007-4772 was both incomplete, in that it didn't handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

- Improve memory-usage accounting in regular-expression compiler (Tom Lane)

This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

- Improve performance of regular-expression compiler (Tom Lane)
- Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)

Previously, `%h/%r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don't need it (Tom Lane, Amit Kapila)

This oversight resulted in failure to recover from crashes whenever `logging_collector` is turned on.

- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

It's not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a `walsender` process would wait indefinitely rather than noticing a loss of connection.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)
- In `psql`, ensure that `libreadline`'s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

Previously, `libreadline` did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

- Fix `psql`'s `\det` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)
- Avoid possible crash in `psql`'s `\c` command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)
- In `pg_ctl start -w`, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, `pg_ctl` relied on an assumption that the new postmaster would always create `postmaster.pid` within five seconds. But that can fail on heavily-loaded systems, causing `pg_ctl` to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a `pg_ctl start -w` done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In `pg_ctl start -w`, don't attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `:::`, because it would try to use that value verbatim as the address to connect to, which doesn't work. Instead assume that `127.0.0.1` or `:::1`, respectively, is the right thing to use.

- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

- In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of `tar` support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in `pg_dump`'s processing of extension member objects (Tom Lane)
- Make `pg_dump` mark a view's triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)
- Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

A relopion value that isn't a simple identifier or number could lead to dump/reload failures due to syntax errors in `CREATE` statements issued by `pg_dump`. This is not an issue with any relopion currently supported by core PostgreSQL, but extensions could allow relopions that cause the problem.

- Avoid repeated password prompts during parallel `pg_dump` (Zeus Kronion)
- Fix `pg_upgrade`'s file-copying code to handle errors properly on Windows (Bruce Momjian)
- Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)
- Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Ioseph Kim)
- Avoid dump/reload problems when using both `plpython2` and `plpython3` (Tom Lane)

In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of `libpython` cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
- Fix premature clearing of `libpq`'s input buffer when socket EOF is seen (Tom Lane)

This mistake caused `libpq` to sometimes not report the backend's final error message before reporting "server closed the connection unexpectedly".

- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

- Improve `libpq`'s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnakangas)
- Fix order of arguments in `ecpg`-generated `typedef` statements (Michael Meskes)
- Use `%g` not `%f` format in `ecpg`'s `PGTYPESnumeric_from_double()` (Tom Lane)
- Fix `ecpg`-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)

Such a comment is rejected by `ecpg`. It's not yet clear whether `ecpg` itself should be changed.

- Fix `hstore_to_json_loose()`'s test for whether an `hstore` value can be converted to a JSON number (Tom Lane)

Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.

- Ensure that `contrib/pgcrypto`'s `crypt()` function can be interrupted by query cancel (Andreas Karlsson)
- In `contrib/postgres_fdw`, fix bugs triggered by use of `tableoid` in data-modifying commands (Etsuro Fujita, Robert Haas)
- Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)

Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.

- Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)

This avoids possible bitwise differences in the produced executable files from one build to the next.

- Install our `missing` script where PGXS builds can find it (Jim Nasby)

This allows sane behavior in a PGXS build done on a machine where build tools such as bison are missing.

- Ensure that `dynloader.h` is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Add variant regression test expected-output file to match behavior of current libxml2 (Tom Lane)

The fix for libxml2's CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we'll probably have to live with it for some time, so work around it.

- Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

## E.55. Release 9.4.5

**Release date:** 2015-10-08

This release contains a variety of fixes from 9.4.4. For information about new features in the 9.4 major release, see Section E.60.

### E.55.1. Migration to Version 9.4.5

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.4, see Section E.56.

### E.55.2. Changes

- Guard against stack overflows in `json` parsing (Oskari Saarenmaa)

If an application constructs PostgreSQL `json` or `jsonb` values from arbitrary user input, the application's users can reliably crash the PostgreSQL server, causing momentary denial of service. (CVE-2015-5289)

- Fix `contrib/pgcrypto` to detect and report too-short `crypt()` salts (Josh Kupershmidt)

Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)

A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix possible deadlock during WAL insertion when `commit_delay` is set (Heikki Linnakangas)
- Ensure all relations referred to by an updatable view are properly locked during an update statement (Dean Rasheed)
- Fix insertion of relations into the relation cache “init file” (Tom Lane)

An oversight in a patch in the most recent minor releases caused `pg_trigger_tgrelid_tgname_index` to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid  $O(N^2)$  behavior when inserting many tuples into a SPI query result (Neil Conway)
- Improve `LISTEN` startup time when there are many unread notifications (Matt Newell)
- Fix performance problem when a session alters large numbers of foreign key constraints (Jan Wieck, Tom Lane)

This was seen primarily when restoring `pg_dump` output for databases with many thousands of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

- Lower the minimum values of the `*_freeze_max_age` parameters (Andres Freund)

This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)
- Avoid logging complaints when a parameter that can only be set at server start appears multiple times in `postgresql.conf`, and fix counting of line numbers after an `include_dir` directive (Tom Lane)
- Fix rare internal overflow in multiplication of `numeric` values (Dean Rasheed)
- Guard against hard-to-reach stack overflows involving record types, range types, `json`, `jsonb`, `tsquery`, `ltxtquery` and `query_int` (Noah Misch)
- Fix handling of `DOW` and `DOY` in datetime input (Greg Stark)

These tokens aren't meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, `SIMILAR TO`, and `LIKE` matching (Tom Lane)

Suitable search patterns and a low stack depth limit could lead to stack-overflow crashes.

- Fix potential infinite loop in regular expression execution (Tom Lane)

A search pattern that can apparently match a zero-length string, but actually doesn't match because of a back reference, could lead to an infinite loop.

- In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)
- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)

- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)
- Fix very-low-probability stack overrun in `qsort` (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)

These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan's variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.

- Improve planner's performance for `UPDATE/DELETE` on large inheritance sets (Tom Lane, Dean Rasheed)
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)

This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.

- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the `postmaster.pid` file (Tom Lane)

This avoids race-condition failures if an external script attempts to start a new postmaster as soon as `pg_ctl stop` returns.

- Ensure that the postmaster does not exit until all its child processes are gone, even in an immediate shutdown (Tom Lane)

Like the previous item, this avoids possible race conditions against a subsequently-started postmaster.

- Fix postmaster's handling of a startup-process crash during crash recovery (Tom Lane)

If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we'd try to launch a new startup process, which typically would just crash again, leading to an infinite loop.

- Make emergency autovacuuming for multixact wraparound more robust (Andres Freund)
- Do not print a `WARNING` when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index's pending-insertions list is interruptable by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)

Such a page might be left behind after a crash.

- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)

`VACUUM` attempted to recycle such pages, but did so in a way that wasn't crash-safe.

- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)

- Fix misreporting of `CONTINUE` and `MOVE` statement types in PL/pgSQL's error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)
- Fix PL/Python crash when returning the string representation of a `record` result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of `malloc()` calls (Michael Paquier, Álvaro Herrera)
- In `contrib/isn`, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)

EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

- Improve `contrib/pg_stat_statements`' handling of query-text garbage collection (Peter Geoghegan)

The external file containing query texts could bloat to very large sizes; once it got past 1GB attempts to trim it would fail, soon leading to situations where the file could not be read at all.

- Improve `contrib/postgres_fdw`'s handling of collation-related decisions (Tom Lane)

The main user-visible effect is expected to be that comparisons involving `varchar` columns will be sent to the remote server for execution in more cases than before.

- Improve `libpq`'s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in `ecpg` (Michael Paquier)
- Fix `psql`'s code for locale-aware formatting of numeric output (Tom Lane)

The formatting code invoked by `\pset numericlocale on` did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the `money` data type.

- Prevent crash in `psql`'s `\c` command when there is no current connection (Noah Misch)
- Make `pg_dump` handle inherited `NOT VALID` check constraints correctly (Tom Lane)
- Fix selection of default `zlib` compression level in `pg_dump`'s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a `pg_dump` run with `tar`-format output are not world-readable (Michael Paquier)
- Fix `pg_dump` and `pg_upgrade` to support cases where the `postgres` or `template1` database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix `pg_dump` to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)

When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, `pg_dump` would produce `GRANT/REVOKE` commands that revoked the owner's grantable privileges and instead granted all privileges to `PUBLIC`. Since the privileges involved are just `USAGE` and `EXECUTE`, this isn't a security problem, but it's certainly a surprising representation of the older systems' behavior. Fix it to leave the default privilege state alone in these cases.

- Fix `pg_dump` to dump shell types (Tom Lane)

Shell types (that is, not-yet-fully-defined types) aren't useful for much, but nonetheless `pg_dump` should dump them.

- Fix assorted minor memory leaks in `pg_dump` and other client-side programs (Michael Paquier)
- Fix `pgbench`'s progress-report behavior when a query, or `pgbench` itself, gets stuck (Fabien Coelho)

- Fix spinlock assembly code for Alpha hardware (Tom Lane)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX's native assembler (Tom Lane)

Building with gcc didn't work if gcc had been configured to use the native assembler, which is becoming more common.

- On AIX, test the `-qlonglong` compiler option rather than just assuming it's safe to use (Noah Misch)
- On AIX, use `-Wl, -brtl1lib` link option to allow symbols to be resolved at runtime (Noah Misch)

Perl relies on this ability in 5.8.0 and later.

- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use `librt` for `sched_yield()` when necessary, which it is on some Solaris versions (Oskari Saarenmaa)
- Translate encoding UHC as Windows code page 949 (Noah Misch)

This fixes presentation of non-ASCII log messages from processes that are not attached to any particular database, such as the postmaster.

- On Windows, avoid failure when doing encoding conversion to UTF16 outside a transaction, such as for log messages (Noah Misch)
- Fix postmaster startup failure due to not copying `setlocale()`'s return value (Noah Misch)

This has been reported on Windows systems with the ANSI code page set to CP936 (“Chinese (Simplified, PRC)”), and may occur with other multibyte code pages.

- Fix Windows `install.bat` script to handle target directory names that contain spaces (Heikki Linakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named `VERSION_NUM` (Michael Paquier)
- Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name `America/Fort_Nelson` for the Canadian Northern Rockies.

## E.56. Release 9.4.4

**Release date:** 2015-06-12

This release contains a small number of fixes from 9.4.3. For information about new features in the 9.4 major release, see Section E.60.

### E.56.1. Migration to Version 9.4.4

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading an installation that was previously upgraded using a `pg_upgrade` version between 9.3.0 and 9.3.4 inclusive, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.4.2, see Section E.58.

### E.56.2. Changes

- Fix possible failure to recover from an inconsistent database state (Robert Haas)

Recent PostgreSQL releases introduced mechanisms to protect against multixact wraparound, but some of that code did not account for the possibility that it would need to run during crash recovery, when the database may not be in a consistent state. This could result in failure to restart after

a crash, or failure to start up a secondary server. The lingering effects of a previously-fixed bug in `pg_upgrade` could also cause such a failure, in installations that had used `pg_upgrade` versions between 9.3.0 and 9.3.4.

The `pg_upgrade` bug in question was that it would set `oldestMultiXid` to 1 in `pg_control` even if the true value should be higher. With the fixes introduced in this release, such a situation will result in immediate emergency autovacuuming until a correct `oldestMultiXid` value can be determined. If that would pose a hardship, users can avoid it by doing manual vacuuming *before* upgrading to this release. In detail:

1. Check whether `pg_control` reports “Latest checkpoint's `oldestMultiXid`” to be 1. If not, there's nothing to do.
  2. Look in `PGDATA/pg_multixact/offsets` to see if there's a file named `0000`. If there is, there's nothing to do.
  3. Otherwise, for each table that has `pg_class.relminmxid` equal to 1, `VACUUM` that table with both `vacuum_multixact_freeze_min_age` and `vacuum_multixact_freeze_table_age` set to zero. (You can use the vacuum cost delay parameters described in Section 20.4.4 to reduce the performance consequences for concurrent sessions.)
- Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a `VACUUM FULL` on a system catalog might fail to update the “init file” that's used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it's so hard to trigger that no reproducible case had been seen until recently.

- Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE` (Tom Lane)

A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

- Improve planner's cost estimates for semi-joins and anti-joins with inner indexscans (Tom Lane, Tomas Vondra)

This type of plan is quite cheap when all the join clauses are used as index scan conditions, even if the inner scan would nominally fetch many rows, because the executor will stop after obtaining one row. The planner only partially accounted for that effect, and would therefore overestimate the cost, leading it to possibly choose some other much less efficient plan type.

## E.57. Release 9.4.3

**Release date:** 2015-06-04

This release contains a small number of fixes from 9.4.2. For information about new features in the 9.4 major release, see Section E.60.

### E.57.1. Migration to Version 9.4.3

A dump/restore is not required for those running 9.4.X.

However, if you are upgrading from a version earlier than 9.4.2, see Section E.58.

### E.57.2. Changes

- Avoid failures while `fsync`'ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)

In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL cer-

tificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

Also apply the same rules in `initdb --sync-only`. This case is less critical but it should act similarly.

- Fix `pg_get_functiondef()` to show functions' `LEAKPROOF` property, if set (Jeevan Chalke)
- Fix `pushJsonbValue()` to unpack `jbvBinary` objects (Andrew Dunstan)

This change does not affect any behavior in the core code as of 9.4, but it avoids a corner case for possible third-party callers.

- Remove `configure`'s check prohibiting linking to a threaded `libpython` on OpenBSD (Tom Lane)

The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

## E.58. Release 9.4.2

**Release date:** 2015-05-22

This release contains a variety of fixes from 9.4.1. For information about new features in the 9.4 major release, see Section E.60.

### E.58.1. Migration to Version 9.4.2

A dump/restore is not required for those running 9.4.X.

However, if you use `contrib/citext`'s `regexp_matches()` functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.4.1, see Section E.59.

### E.58.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)

Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn't been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

It remains possible that some calls of the `*printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it's unknown whether `pgcrypto`'s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Protect against wraparound of multixact member IDs (Álvaro Herrera, Robert Haas, Thomas Munro)

Under certain usage patterns, the existing defenses against this might be insufficient, allowing `pg_multixact/members` files to be removed too early, resulting in data loss. The fix for this includes modifying the server to fail transactions that would result in overwriting old multixact member ID data, and improving autovacuum to ensure it will act proactively to prevent multixact member ID wraparound, as it does for transaction ID wraparound.

- Fix incorrect declaration of `contrib/citext`'s `regexp_matches()` functions (Tom Lane)

These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the `citext` extension, while we have provided corrected declarations in version 1.1 (which is *not* installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO '1.1'` in each database in which `citext` is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use `citext`'s `regexp_matches()` functions.

- Render infinite dates and timestamps as `infinity` when converting to `json`, rather than throwing an error (Andrew Dunstan)
- Fix `json/jsonb`'s `populate_record()` and `to_record()` functions to handle empty input properly (Andrew Dunstan)
- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)

If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- Fix behavior when changing foreign key constraint deferrability status with `ALTER TABLE ... ALTER CONSTRAINT` (Tom Lane)

Operations later in the same session or concurrent sessions might not honor the status change promptly.

- Fix planning of star-schema-style queries (Tom Lane)

Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)

This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)

Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)

This oversight has been seen to lead to “failed to join all relations together” errors in queries involving `LATERAL`, and that might happen in other cases as well.

- Ensure that row locking occurs properly when the target of an `UPDATE` or `DELETE` is a security-barrier view (Stephen Frost)
- Use a file opened for read/write when syncing replication slot data during database startup (Andres Freund)

On some platforms, the previous coding could result in errors like “could not fsync file “pg\_replslot/...”: Bad file descriptor”.

- Fix possible deadlock at startup when `max_prepared_transactions` is too small (Heikki Linnakangas)
- Don't archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)
- Recursively `fsync()` the data directory after a crash (Abhijit Menon-Sen, Robert Haas)

This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

- Fix autovacuum launcher's possible failure to shut down, if an error occurs after it receives `SIGTERM` (Álvaro Herrera)
- Fix failure to handle invalidation messages for system catalogs early in session startup (Tom Lane)

This oversight could result in failures in sessions that start concurrently with a `VACUUM FULL` on a system catalog.

- Fix crash in `BackendIdGetTransactionIds()` when trying to get status for a backend process that just exited (Tom Lane)
- Cope with unexpected signals in `LockBufferForCleanup()` (Andres Freund)

This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.

- Fix crash when doing `COPY IN` to a table with check constraints that contain whole-row references (Tom Lane)

The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)

Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

- Avoid busy-waiting with short `recovery_min_apply_delay` values (Andres Freund)
- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)
- Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)
- Fix memory leaks in GIN index vacuum (Heikki Linnakangas)
- Check for interrupts while analyzing index expressions (Jeff Janes)

`ANALYZE` executes index expressions many times; if there are slow functions in such an expression, it's desirable to be able to cancel the `ANALYZE` before that loop finishes.

- Ensure `tableoid` of a foreign table is reported correctly when a `READ COMMITTED` recheck occurs after locking rows in `SELECT FOR UPDATE`, `UPDATE`, or `DELETE` (Etsuro Fujita)
- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)
- Include the schema name in object identity strings for conversions (Álvaro Herrera)
- Recommend setting `include_realm` to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)

Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 `pg_hba.conf` entries to IPv4-in-IPv6 addresses (Tom Lane)

This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it's not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let's just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 `pg_hba.conf` entries, which does not seem like a good thing to do in minor releases.)

- Fix status reporting for terminated background workers that were never actually started (Robert Haas)
- After a database crash, don't restart background workers that are marked `BGW_NEVER_RESTART` (Amit Khandekar)
- Report WAL flush, not insert, position in `IDENTIFY_SYSTEM` replication command (Heikki Linnakangas)

This avoids a possible startup failure in `pg_receivexlog`.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that `pg_ctl` will wait for shutdown (Krystian Bigaj)
- Reduce risk of network deadlock when using libpq's non-blocking mode (Heikki Linnakangas)

When sending large volumes of data, it's important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of NOTICE messages during `COPY FROM STDIN`.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We've modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call `PQconsumeInput()` upon read-ready.

- In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)
- Fix array handling in `ecpg` (Michael Meskes)
- Fix `psql` to sanely handle URIs and `conninfo` strings as the first parameter to `\connect` (David Fetter, Andrew Dunstan, Álvaro Herrera)

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

- Suppress incorrect complaints from `psql` on some platforms that it failed to write `~/.psql_history` at exit (Tom Lane)

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

- Fix `pg_dump`'s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)
- In `pg_dump`, fix failure to honor `-Z` compression level option together with `-Fd` (Michael Paquier)
- Make `pg_dump` consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)

This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

- Avoid possible `pg_dump` failure when concurrent sessions are creating and dropping temporary functions (Tom Lane)
- Fix dumping of views that are just `VALUES (...)` but have column aliases (Tom Lane)
- Ensure that a view's replication identity is correctly set to `nothing` during dump/restore (Marko Tiikkaja)

Previously, if the view was involved in a circular dependency, it might wind up with an incorrect replication identity property.

- In `pg_upgrade`, force timeline 1 in the new cluster (Bruce Momjian)

This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

- In `pg_upgrade`, check for improperly non-connectable databases before proceeding (Bruce Momjian)
- In `pg_upgrade`, quote directory paths properly in the generated `delete_old_cluster` script (Bruce Momjian)
- In `pg_upgrade`, preserve database-level freezing info properly (Bruce Momjian)

This oversight could cause missing-clog-file errors for tables within the `postgres` and `template1` databases.

- Run `pg_upgrade` and `pg_resetxlog` with restricted privileges on Windows, so that they don't fail when run by an administrator (Muhammad Asif Naeem)
- Improve handling of `readdir()` failures when scanning directories in `initdb` and `pg_basebackup` (Marco Nenciarini)
- Fix slow sorting algorithm in `contrib/intarray` (Tom Lane)
- Fix compile failure on Sparc V8 machines (Rob Rowan)
- Silence some build warnings on macOS (Tom Lane)
- Update time zone data files to `tzdata` release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

## E.59. Release 9.4.1

**Release date:** 2015-02-05

This release contains a variety of fixes from 9.4.0. For information about new features in the 9.4 major release, see Section E.60.

### E.59.1. Migration to Version 9.4.1

A dump/restore is not required for those running 9.4.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)\_Norway” or “norwegian-bokmal” locale

names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian\_Norway”. For details see [http://wiki.postgresql.org/wiki/Changes\\_To\\_Norwegian\\_Locale](http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale)

## E.59.2. Changes

- Fix buffer overruns in `to_char()` (Bruce Momjian)

When `to_char()` processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- Fix buffer overrun in replacement `*printf()` functions (Tom Lane)

PostgreSQL includes a replacement implementation of `printf` and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers `e`, `E`, `f`, `F`, `g` or `G`) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use `printf`-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)

Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)

If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message's data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)

Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have `SELECT` privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing's temporary installations on Windows (Noah Misch)

Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named “Norwegian (Bokmål)” (Heikki Linnakangas)

Non-ASCII locale names are problematic since it's not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, “Norwegian\_Norway”.

9.4.0 mapped the troublesome name to “norwegian-bokmal”, but that turns out not to work on all Windows configurations. “Norwegian\_Norway” is now recommended instead.

- Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)

In `READ COMMITTED` mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Avoid possible deadlock while trying to acquire tuple locks in EvalPlanQual processing (Álvaro Herrera, Mark Kirkwood)
- Fix failure to wait when a transaction tries to acquire a `FOR NO KEY EXCLUSIVE` tuple lock, while multiple other transactions currently hold `FOR SHARE` locks (Álvaro Herrera)
- Improve performance of `EXPLAIN` with large range tables (Tom Lane)
- Fix `jsonb` Unicode escape processing, and in consequence disallow `\u0000` (Tom Lane)

Previously, the JSON Unicode escape `\u0000` was accepted and was stored as those six characters; but that is indistinguishable from what is stored for the input `\\u0000`, resulting in ambiguity. Moreover, in cases where de-escaped textual output is expected, such as the `->>` operator, the sequence was printed as `\u0000`, which does not meet the expectation that JSON escaping would be removed. (Consistent behavior would require emitting a zero byte, but PostgreSQL does not support zero bytes embedded in text strings.) 9.4.0 included an ill-advised attempt to improve this situation by adjusting JSON output conversion rules; but of course that could not fix the fundamental ambiguity, and it turned out to break other usages of Unicode escape sequences. Revert that, and to avoid the core problem, reject `\u0000` in `jsonb` input.

If a `jsonb` column contains a `\u0000` value stored with 9.4.0, it will henceforth read out as though it were `\\u0000`, which is the other valid interpretation of the data stored by 9.4.0 for this case.

The `json` type did not have the storage-ambiguity problem, but it did have the problem of inconsistent de-escaped textual output. Therefore `\u0000` will now also be rejected in `json` values when conversion to de-escaped form is required. This change does not break the ability to store `\u0000` in `json` columns so long as no processing is done on the values. This is exactly parallel to the cases in which non-ASCII Unicode escapes are allowed when the database encoding is not UTF8.

- Fix namespace handling in `xpath()` (Ali Akbar)

Previously, the `xml` value resulting from an `xpath()` call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input `xml` value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

- Fix assorted oversights in range-operator selectivity estimation (Emre Hasegeli)

This patch fixes corner-case “unexpected operator NNNN” planner errors, and improves the selectivity estimates for some other cases.

- Revert unintended reduction in maximum size of a GIN index item (Heikki Linnakangas)

9.4.0 could fail with “index row size exceeds maximum” errors for data that previous versions would accept.

- Fix query-duration memory leak during repeated GIN index rescans (Heikki Linnakangas)
- Fix possible crash when using nonzero `gin_fuzzy_search_limit` (Heikki Linnakangas)
- Assorted fixes for logical decoding (Andres Freund)
- Fix incorrect replay of WAL parameter change records that report changes in the `wal_log_hints` setting (Petr Jelinek)
- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)

This message was originally thought to be essentially a can't-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a

bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

- Warn if macOS's `setlocale()` starts an unwanted extra thread inside the postmaster (Noah Misch)
- Fix libpq's behavior when `/etc/passwd` isn't readable (Tom Lane)

While doing `PQsetdbLogin()`, libpq attempts to ascertain the user's operating system name, which on most Unix platforms involves reading `/etc/passwd`. As of 9.4, failure to do that was treated as a hard error. Restore the previous behavior, which was to fail only if the application does not provide a database role name to connect as. This supports operation in chroot environments that lack an `/etc/passwd` file.

- Improve consistency of parsing of psql's special variables (Tom Lane)

Allow variant spellings of `on` and `off` (such as `1/0`) for `ECHO_HIDDEN` and `ON_ERROR_ROLLBACK`. Report a warning for unrecognized values for `COMP_KEYWORD_CASE`, `ECHO`, `ECHO_HIDDEN`, `HISTCONTROL`, `ON_ERROR_ROLLBACK`, and `VERBOSEITY`. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Fix `pg_dump` to handle comments on event triggers without failing (Tom Lane)
- Allow parallel `pg_dump` to use `--serializable-deferrable` (Kevin Grittner)
- Prevent WAL files created by `pg_basebackup -x/-X` from being archived again when the standby is promoted (Andres Freund)
- Handle unexpected query results, especially NULLs, safely in `contrib/tablefunc`'s `connectby()` (Michael Paquier)

`connectby()` previously crashed if it encountered a NULL key value. It now prints that row but doesn't recurse further.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)

These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

- Allow `CFLAGS` from `configure`'s environment to override automatically-supplied `CFLAGS` (Tom Lane)

Previously, `configure` would add any switches that it chose of its own accord to the end of the user-specified `CFLAGS` string. Since most compilers process switches left-to-right, this meant that `configure`'s choices would override the user-specified flags in case of conflicts. That should work the other way around, so adjust the logic to put the user's string at the end not the beginning.

- Make `pg_regress` remove any temporary installation it created upon successful exit (Tom Lane)

This results in a very substantial reduction in disk space usage during `make check-world`, since that sequence involves creation of numerous temporary installations.

- Add CST (China Standard Time) to our lists of timezone abbreviations (Tom Lane)
- Update time zone data files to tzdata release 2015a for DST law changes in Chile and Mexico, plus historical changes in Iceland.

## E.60. Release 9.4

**Release date:** 2014-12-18

### E.60.1. Overview

Major enhancements in PostgreSQL 9.4 include:

- Add `jsonb`, a more capable and efficient data type for storing JSON data

- Add new SQL command ALTER SYSTEM for changing `postgresql.conf` configuration file entries
- Reduce lock strength for some ALTER TABLE commands
- Allow materialized views to be refreshed without blocking concurrent reads
- Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format
- Allow background worker processes to be dynamically registered, started and terminated

The above items are explained in more detail in the sections below.

## E.60.2. Migration to Version 9.4

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.4 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Tighten checks for multidimensional array input (Bruce Momjian)

Previously, an input array string that started with a single-element sub-array could later contain multi-element sub-arrays, e.g. `'{{1}, {2,3}}'::int[]` would be accepted.

- When converting values of type `date`, `timestamp` or `timestampz` to JSON, render the values in a format compliant with ISO 8601 (Andrew Dunstan)

Previously such values were rendered according to the current `DateStyle` setting; but many JSON processors require timestamps to be in ISO 8601 format. If necessary, the previous behavior can be obtained by explicitly casting the datetime value to `text` before passing it to the JSON conversion function.

- The `json #> text[]` path extraction operator now returns its lefthand input, not NULL, if the array is empty (Tom Lane)

This is consistent with the notion that this represents zero applications of the simple field/element extraction operator `->`. Similarly, `json #>> text[]` with an empty array merely coerces its lefthand input to `text`.

- Corner cases in the JSON field/element/path extraction operators now return NULL rather than raising an error (Tom Lane)

For example, applying field extraction to a JSON array now yields NULL not an error. This is more consistent (since some comparable cases such as `no-such-field` already returned NULL), and it makes it safe to create expression indexes that use these operators, since they will now not throw errors for any valid JSON input.

- Cause consecutive whitespace in `to_timestamp()` and `to_date()` format strings to consume a corresponding number of characters in the input string (whitespace or not), then conditionally consume adjacent whitespace, if not in `FX` mode (Jeevan Chalke)

Previously, consecutive whitespace characters in a non-`FX` format string behaved like a single whitespace character and consumed all adjacent whitespace in the input string. For example, previously a format string of three spaces would consume only the first space in `' 12'`, but it will now consume all three characters.

- Fix `ts_rank_cd()` to ignore stripped lexemes (Alex Hill)

Previously, stripped lexemes were treated as if they had a default location, producing a rank of dubious usefulness.

- For functions declared to take `VARIADIC "any"`, an actual parameter marked as `VARIADIC` must be of a determinable array type (Pavel Stehule)

Such parameters can no longer be written as an undecorated string literal or `NULL`; a cast to an appropriate array data type will now be required. Note that this does not affect parameters not marked `VARIADIC`.

- Ensure that whole-row variables expose the expected column names to functions that pay attention to column names within composite arguments (Tom Lane)

Constructs like `row_to_json(tab.*)` now always emit column names that match the column aliases visible for table `tab` at the point of the call. In previous releases the emitted column names would sometimes be the table's actual column names regardless of any aliases assigned in the query.

- `DISCARD` now also discards sequence-related state (Fabrízio de Royes Mello, Robert Haas)
- Rename `EXPLAIN ANALYZE`'s “total runtime” output to “execution time” (Tom Lane)

Now that planning time is also reported, the previous name was confusing.

- `SHOW TIME ZONE` now outputs simple numeric UTC offsets in POSIX timezone format (Tom Lane)

Previously, such timezone settings were displayed as `interval` values. The new output is properly interpreted by `SET TIME ZONE` when passed as a simple string, whereas the old output required special treatment to be re-parsed correctly.

- Foreign data wrappers that support updating foreign tables must consider the possible presence of `AFTER ROW` triggers (Noah Misch)

When an `AFTER ROW` trigger is present, all columns of the table must be returned by updating actions, since the trigger might inspect any or all of them. Previously, foreign tables never had triggers, so the FDW might optimize away fetching columns not mentioned in the `RETURNING` clause (if any).

- Prevent `CHECK` constraints from referencing system columns, except `tableoid` (Amit Kapila)

Previously such check constraints were allowed, but they would often cause errors during restores.

- Use the last specified recovery target parameter if multiple target parameters are specified (Heikki Linnakangas)

Previously, there was an undocumented precedence order among the `recovery_target_XXX` parameters.

- On Windows, automatically preserve quotes in command strings supplied by the user (Heikki Linnakangas)

User commands that did their own quote preservation might need adjustment. This is likely to be an issue for commands used in `archive_command`, `restore_command`, and `COPY TO/FROM PROGRAM`.

- Remove catalog column `pg_class.reltoastidxid` (Michael Paquier)
- Remove catalog column `pg_rewrite.ev_attr` (Kevin Grittner)

Per-column rules have not been supported since PostgreSQL 7.3.

- Remove native support for Kerberos authentication (`--with-krb5`, etc) (Magnus Hagander)

The supported way to use Kerberos authentication is with GSSAPI. The native code has been deprecated since PostgreSQL 8.3.

- In PL/Python, handle domains over arrays like the underlying array type (Rodolfo Campero)

Previously such values were treated as strings.

- Make `libpq's PQconnectdbParams()` and `PQpingParams()` functions process zero-length strings as defaults (Adrian Vondendriesch)

Previously, these functions treated zero-length string values as selecting the default in only some cases.

- Change empty arrays returned by the `intarray` module to be zero-dimensional arrays (Bruce Momjian)

Previously, empty arrays were returned as zero-length one-dimensional arrays, whose text representation looked the same as zero-dimensional arrays (`{ }`), but they acted differently in array operations. `intarray`'s behavior in this area now matches the built-in array operators.

- `pg_upgrade` now uses `-U` or `--username` to specify the user name (Bruce Momjian)

Previously this option was spelled `-u` or `--user`, but that was inconsistent with other tools.

### E.60.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.4 and the previous major release.

#### E.60.3.1. Server

- Allow background worker processes to be dynamically registered, started and terminated (Robert Haas)

The new `worker_spi` module shows an example of use of this feature.

- Allow dynamic allocation of shared memory segments (Robert Haas, Amit Kapila)

This feature is illustrated in the `test_shm_mq` module.

- During crash recovery or immediate shutdown, send uncatchable termination signals (SIGKILL) to child processes that do not shut down promptly (MauMau, Álvaro Herrera)

This reduces the likelihood of leaving orphaned child processes behind after postmaster shutdown, as well as ensuring that crash recovery can proceed if some child processes have become “stuck”.

- Improve randomness of the database system identifier (Tom Lane)
- Make VACUUM properly report dead but not-yet-removable rows to the statistics collector (Hari Babu)

Previously these were reported as live rows.

##### E.60.3.1.1. Indexes

- Reduce GIN index size (Alexander Korotkov, Heikki Linnakangas)

Indexes upgraded via `pg_upgrade` will work fine but will still be in the old, larger GIN format. Use `REINDEX` to recreate old GIN indexes in the new format.

- Improve speed of multi-key GIN lookups (Alexander Korotkov, Heikki Linnakangas)
- Add GiST index support for `inet` and `cidr` data types (Emre Hasegeli)

Such indexes improve subnet and supernet lookups and ordering comparisons.

- Fix rare race condition in B-tree page deletion (Heikki Linnakangas)
- Make the handling of interrupted B-tree page splits more robust (Heikki Linnakangas)

##### E.60.3.1.2. General Performance

- Allow multiple backends to insert into WAL buffers concurrently (Heikki Linnakangas)

This improves parallel write performance.

- Conditionally write only the modified portion of updated rows to WAL (Amit Kapila)
- Improve performance of aggregate functions used as window functions (David Rowley, Florian Pflug, Tom Lane)
- Improve speed of aggregates that use `numeric` state values (Hadi Moshayedi)
- Attempt to freeze tuples when tables are rewritten with `CLUSTER` or `VACUUM FULL` (Robert Haas, Andres Freund)

This can avoid the need to freeze the tuples in the future.

- Improve speed of `COPY` with default `nextval()` columns (Simon Riggs)
- Improve speed of accessing many different sequences in the same session (David Rowley)
- Raise hard limit on the number of tuples held in memory during sorting and B-tree index builds (Noah Misch)
- Reduce memory allocated by PL/pgSQL `DO` blocks (Tom Lane)
- Make the planner more aggressive about extracting restriction clauses from mixed `AND/OR` clauses (Tom Lane)
- Disallow pushing volatile `WHERE` clauses down into `DISTINCT` subqueries (Tom Lane)

Pushing down a `WHERE` clause can produce a more efficient plan overall, but at the cost of evaluating the clause more often than is implied by the text of the query; so don't do it if the clause contains any volatile functions.

- Auto-resize the catalog caches (Heikki Linnakangas)

This reduces memory consumption for sessions accessing only a few tables, and improves performance for sessions accessing many tables.

#### **E.60.3.1.3. Monitoring**

- Add `pg_stat_archiver` system view to report WAL archiver activity (Gabriele Bartolini)
- Add `n_mod_since_analyze` columns to `pg_stat_all_tables` and related system views (Mark Kirkwood)

These columns expose the system's estimate of the number of changed tuples since the table's last `ANALYZE`. This estimate drives decisions about when to auto-analyze.

- Add `backend_xid` and `backend_xmin` columns to the system view `pg_stat_activity`, and a `backend_xmin` column to `pg_stat_replication` (Christian Kruse)

#### **E.60.3.1.4. SSL**

- Add support for SSL ECDH key exchange (Marko Kreen)

This allows use of Elliptic Curve keys for server authentication. Such keys are faster and have better security than RSA keys. The new configuration parameter `ssl_ecdh_curve` controls which curve is used for ECDH.

- Improve the default `ssl_ciphers` setting (Marko Kreen)
- By default, the server not the client now controls the preference order of SSL ciphers (Marko Kreen)

Previously, the order specified by `ssl_ciphers` was usually ignored in favor of client-side defaults, which are not configurable in most PostgreSQL clients. If desired, the old behavior can be restored via the new configuration parameter `ssl_prefer_server_ciphers`.

- Make `log_connections` show SSL encryption information (Andreas Kunert)

- Improve SSL renegotiation handling (Álvaro Herrera)

### **E.60.3.1.5. Server Settings**

- Add new SQL command ALTER SYSTEM for changing `postgresql.conf` configuration file entries (Amit Kapila)

Previously such settings could only be changed by manually editing `postgresql.conf`.

- Add `autovacuum_work_mem` configuration parameter to control the amount of memory used by autovacuum workers (Peter Geoghegan)
- Add `huge_pages` parameter to allow using huge memory pages on Linux (Christian Kruse, Richard Poole, Abhijit Menon-Sen)

This can improve performance on large-memory systems.

- Add `max_worker_processes` parameter to limit the number of background workers (Robert Haas)

This is helpful in configuring a standby server to have the required number of worker processes (the same as the primary).

- Add superuser-only `session_preload_libraries` parameter to load libraries at session start (Peter Eisentraut)

In contrast to `local_preload_libraries`, this parameter can load any shared library, not just those in the `$libdir/plugins` directory.

- Add `wal_log_hints` parameter to enable WAL logging of hint-bit changes (Sawada Masahiko)

Hint bit changes are not normally logged, except when checksums are enabled. This is useful for external tools like `pg_rewind`.

- Increase the default settings of `work_mem` and `maintenance_work_mem` by four times (Bruce Momjian)

The new defaults are 4MB and 64MB respectively.

- Increase the default setting of `effective_cache_size` to 4GB (Bruce Momjian, Tom Lane)
- Allow `printf`-style space padding to be specified in `log_line_prefix` (David Rowley)
- Allow terabyte units (`TB`) to be used when specifying configuration variable values (Simon Riggs)
- Show PIDs of lock holders and waiters and improve information about relations in `log_lock_waits` log messages (Christian Kruse)
- Reduce server logging level when loading shared libraries (Peter Geoghegan)

The previous level was `LOG`, which was too verbose for libraries loaded per-session.

- On Windows, make `SQL_ASCII`-encoded databases and server processes (e.g., postmaster) emit messages in the character encoding of the server's Windows user locale (Alexander Law, Noah Misch)

Previously these messages were output in the Windows ANSI code page.

### **E.60.3.2. Replication and Recovery**

- Add replication slots to coordinate activity on streaming standbys with the node they are streaming from (Andres Freund, Robert Haas)

Replication slots allow preservation of resources like WAL files on the primary until they are no longer needed by standby servers.

- Add recovery parameter `recovery_min_apply_delay` to delay replication (Robert Haas, Fabrízio de Royes Mello, Simon Riggs)

Delaying replay on standby servers can be useful for recovering from user errors.

- Add `recovery_target` option `immediate` to stop WAL recovery as soon as a consistent state is reached (MauMau, Heikki Linnakangas)
- Improve recovery target processing (Heikki Linnakangas)

The timestamp reported by `pg_last_xact_replay_timestamp()` now reflects already-committed records, not transactions about to be committed. Recovering to a restore point now replays the restore point, rather than stopping just before the restore point.

- `pg_switch_xlog()` now clears any unused trailing space in the old WAL file (Heikki Linnakangas)

This improves the compression ratio for WAL files.

- Report failure return codes from external recovery commands (Peter Eisentraut)
- Reduce spinlock contention during WAL replay (Heikki Linnakangas)
- Write WAL records of running transactions more frequently (Andres Freund)

This allows standby servers to start faster and clean up resources more aggressively.

#### **E.60.3.2.1. Logical Decoding**

Logical decoding allows database changes to be streamed in a configurable format. The data is read from the WAL and transformed into the desired target format. To implement this feature, the following changes were made:

- Add support for logical decoding of WAL data, to allow database changes to be streamed out in a customizable format (Andres Freund)
- Add new `wal_level` setting `logical` to enable logical change-set encoding in WAL (Andres Freund)
- Add table-level parameter `REPLICA IDENTITY` to control logical replication (Andres Freund)
- Add relation option `user_catalog_table` to identify user-created tables involved in logical change-set encoding (Andres Freund)
- Add `pg_recvlogical` application to receive logical-decoding data (Andres Freund)
- Add `test_decoding` module to illustrate logical decoding at the SQL level (Andres Freund)

#### **E.60.3.3. Queries**

- Add `WITH ORDINALITY` syntax to number the rows returned from a set-returning function in the `FROM` clause (Andrew Gierth, David Fetter)

This is particularly useful for functions like `unnest()`.

- Add `ROWS FROM()` syntax to allow horizontal concatenation of set-returning functions in the `FROM` clause (Andrew Gierth)
- Allow `SELECT` to have an empty target list (Tom Lane)

This was added so that views that select from a table with zero columns can be dumped and restored correctly.

- Ensure that `SELECT ... FOR UPDATE NOWAIT` does not wait in corner cases involving already-concurrently-updated tuples (Craig Ringer and Thomas Munro)

#### **E.60.3.4. Utility Commands**

- Add `DISCARD SEQUENCES` command to discard cached sequence-related state (Fabrízio de Royes Mello, Robert Haas)

`DISCARD ALL` will now also discard such information.

- Add `FORCE NULL` option to `COPY FROM`, which causes quoted strings matching the specified null string to be converted to `NULLs` in `CSV` mode (Ian Barwick, Michael Paquier)

Without this option, only unquoted matching strings will be imported as null values.

- Issue warnings for commands used outside of transaction blocks when they can have no effect (Bruce Momjian)

New warnings are issued for `SET LOCAL`, `SET CONSTRAINTS`, `SET TRANSACTION` and `ABORT` when used outside a transaction block.

- Make `EXPLAIN ANALYZE` show planning time (Andreas Karlsson)
- Make `EXPLAIN` show the grouping columns in `Agg` and `Group` nodes (Tom Lane)
- Make `EXPLAIN ANALYZE` show exact and lossy block counts in bitmap heap scans (Etsuro Fujita)

#### E.60.3.4.2. Views

- Allow a materialized view to be refreshed without blocking other sessions from reading the view meanwhile (Kevin Grittner)

This is done with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

- Allow views to be automatically updated even if they contain some non-updatable columns (Dean Rasheed)

Previously the presence of non-updatable output columns such as expressions, literals, and function calls prevented automatic updates. Now `INSERTs`, `UPDATEs` and `DELETEs` are supported, provided that they do not attempt to assign new values to any of the non-updatable columns.

- Allow control over whether `INSERTs` and `UPDATEs` can add rows to an auto-updatable view that would not appear in the view (Dean Rasheed)

This is controlled with the new `CREATE VIEW` clause `WITH CHECK OPTION`.

- Allow security barrier views to be automatically updatable (Dean Rasheed)

#### E.60.3.5. Object Manipulation

- Support triggers on foreign tables (Ronan Dunklau)
- Allow moving groups of objects from one tablespace to another using the `ALL IN TABLESPACE ... SET TABLESPACE` form of `ALTER TABLE`, `ALTER INDEX`, or `ALTER MATERIALIZED VIEW` (Stephen Frost)
- Allow changing foreign key constraint deferrability via `ALTER TABLE ... ALTER CONSTRAINT` (Simon Riggs)
- Reduce lock strength for some `ALTER TABLE` commands (Simon Riggs, Noah Misch, Robert Haas)

Specifically, `VALIDATE CONSTRAINT`, `CLUSTER ON`, `SET WITHOUT CLUSTER`, `ALTER COLUMN SET STATISTICS`, `ALTER COLUMN SET (attribute_option)`, `ALTER COLUMN RESET (attribute_option)` no longer require `ACCESS EXCLUSIVE` locks.

- Allow tablespace options to be set in `CREATE TABLESPACE` (Vik Fearing)

Formerly these options could only be set via `ALTER TABLESPACE`.

- Allow `CREATE AGGREGATE` to define the estimated size of the aggregate's transition state data (Hadi Moshayedi)

Proper use of this feature allows the planner to better estimate how much memory will be used by aggregates.

- Fix `DROP IF EXISTS` to avoid errors for non-existent objects in more cases (Pavel Stehule, Dean Rasheed)
- Improve how system relations are identified (Andres Freund, Robert Haas)

Previously, relations once moved into the `pg_catalog` schema could no longer be modified or dropped.

### E.60.3.6. Data Types

- Fully implement the `line` data type (Peter Eisentraut)

The `line segment` data type (`lseg`) has always been fully supported. The previous `line` data type (which was enabled only via a compile-time option) is not binary or dump-compatible with the new implementation.

- Add `pg_lsn` data type to represent a WAL log sequence number (LSN) (Robert Haas, Michael Paquier)
- Allow single-point `polygons` to be converted to `circles` (Bruce Momjian)
- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)

Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as `EST`) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

- Allow 5+ digit years for non-ISO `timestamp` and `date` strings, where appropriate (Bruce Momjian)
- Add checks for overflow/underflow of `interval` values (Bruce Momjian)

#### E.60.3.6.1. JSON

- Add `jsonb`, a more capable and efficient data type for storing JSON data (Oleg Bartunov, Teodor Sigaev, Alexander Korotkov, Peter Geoghegan, Andrew Dunstan)

This new type allows faster access to values within a JSON document, and faster and more useful indexing of JSON columns. Scalar values in `jsonb` documents are stored as appropriate scalar SQL types, and the JSON document structure is pre-parsed rather than being stored as text as in the original `json` data type.

- Add new JSON functions to allow for the construction of arbitrarily complex JSON trees (Andrew Dunstan, Laurence Rowe)

New functions include `json_array_elements_text()`, `json_build_array()`, `json_object()`, `json_object_agg()`, `json_to_record()`, and `json_to_recordset()`.

- Add `json_typeof()` to return the data type of a `json` value (Andrew Tipton)

#### E.60.3.7. Functions

- Add `pg_sleep_for(interval)` and `pg_sleep_until(timestamp)` to specify delays more flexibly (Vik Fearing, Julien Rouhaud)

The existing `pg_sleep()` function only supports delays specified in seconds.

- Add `cardinality()` function for arrays (Marko Tiikkaja)

This returns the total number of elements in the array, or zero for an array with no elements.

- Add SQL functions to allow large object reads/writes at arbitrary offsets (Pavel Stehule)

- Allow `unnest()` to take multiple arguments, which are individually unnested then horizontally concatenated (Andrew Gierth)
- Add functions to construct `times`, `dates`, `timestamps`, `timestampz`s, and `intervals` from individual values, rather than strings (Pavel Stehule)

These functions' names are prefixed with `make_`, e.g. `make_date()`.

- Make `to_char()`'s TZ format specifier return a useful value for simple numeric time zone offsets (Tom Lane)

Previously, `to_char(CURRENT_TIMESTAMP, 'TZ')` returned an empty string if the `timezone` was set to a constant like `-4`.

- Add `timezone` offset format specifier `OF` to `to_char()` (Bruce Momjian)
- Improve the random seed used for `random()` (Honza Horak)
- Tighten validity checking for Unicode code points in `chr(int)` (Tom Lane)

This function now only accepts values that are valid UTF8 characters according to RFC 3629.

#### **E.60.3.7.1. System Information Functions**

- Add functions for looking up objects in `pg_class`, `pg_proc`, `pg_type`, and `pg_operator` that do not generate errors for non-existent objects (Yugo Nagata, Nozomi Anzai, Robert Haas)

For example, `to_regclass()` does a lookup in `pg_class` similarly to the `regclass` input function, but it returns `NULL` for a non-existent object instead of failing.

- Add function `pg_filenode_relation()` to allow for more efficient lookup of relation names from filenodes (Andres Freund)
- Add `parameter_default` column to `information_schema.parameters` view (Peter Eisentraut)
- Make `information_schema.schemata` show all accessible schemas (Peter Eisentraut)

Previously it only showed schemas owned by the current user.

#### **E.60.3.7.2. Aggregates**

- Add control over which rows are passed into aggregate functions via the `FILTER` clause (David Fetter)
- Support ordered-set (`WITHIN GROUP`) aggregates (Atri Sharma, Andrew Gierth, Tom Lane)
- Add standard ordered-set aggregates `percentile_cont()`, `percentile_disc()`, `mode()`, `rank()`, `dense_rank()`, `percent_rank()`, and `cume_dist()` (Atri Sharma, Andrew Gierth)
- Support `VARIADIC` aggregate functions (Tom Lane)
- Allow polymorphic aggregates to have non-polymorphic state data types (Tom Lane)

This allows proper declaration in SQL of aggregates like the built-in aggregate `array_agg()`.

#### **E.60.3.8. Server-Side Languages**

- Add event trigger support to PL/Perl and PL/Tcl (Dimitri Fontaine)
- Convert numeric values to decimal in PL/Python (Szymon Guz, Ronan Dunklau)

Previously such values were converted to Python `float` values, risking loss of precision.

##### **E.60.3.8.1. PL/pgSQL Server-Side Language**

- Add ability to retrieve the current PL/pgSQL call stack using `GET DIAGNOSTICS` (Pavel Stehule, Stephen Frost)

- Add option `print_strict_params` to display the parameters passed to a query that violated a `STRICT` constraint (Marko Tiikkaja)
- Add variables `plpgsql.extra_warnings` and `plpgsql.extra_errors` to enable additional PL/pgSQL warnings and errors (Marko Tiikkaja, Petr Jelinek)

Currently only warnings/errors about shadowed variables are available.

### E.60.3.9. libpq

- Make libpq's `PQconnndefaults()` function ignore invalid service files (Steve Singer, Bruce Momjian)  
Previously it returned `NULL` if an incorrect service file was encountered.
- Accept TLS protocol versions beyond `TLSv1` in libpq (Marko Kreen)

### E.60.3.10. Client Applications

- Add `createuser` option `-g` to specify role membership (Christopher Browne)
- Add `vacuumdb` option `--analyze-in-stages` to analyze in stages of increasing granularity (Peter Eisentraut)

This allows minimal statistics to be created quickly.

- Make `pg_resetlog` with option `-n` output current and potentially changed values (Rajeev Rastogi)
- Make `initdb` throw error for incorrect locale settings, rather than silently falling back to a default choice (Tom Lane)
- Make `pg_ctl` return exit code 4 for an inaccessible data directory (Amit Kapila, Bruce Momjian)

This behavior more closely matches the Linux Standard Base (LSB) Core Specification.

- On Windows, ensure that a non-absolute `-D` path specification is interpreted relative to `pg_ctl`'s current directory (Kumar Rajeev Rastogi)

Previously it would be interpreted relative to whichever directory the underlying Windows service was started in.

- Allow `sizeof()` in ECPG C array definitions (Michael Meskes)
- Make ECPG properly handle nesting of C-style comments in both C and SQL text (Michael Meskes)
- Suppress “No rows” output in `psql` expanded mode when the footer is disabled (Bruce Momjian)
- Allow Control-C to abort `psql` when it's hung at connection startup (Peter Eisentraut)

#### 1. Backslash Commands

- Make `psql`'s `\db+` show tablespace options (Magnus Hagander)
- Make `\do+` display the functions that implement the operators (Marko Tiikkaja)
- Make `\d+` output an `OID` line only if an `oid` column exists in the table (Bruce Momjian)

Previously, the presence or absence of an `oid` column was always reported.

- Make `\d` show disabled system triggers (Bruce Momjian)

Previously, if you disabled all triggers, only user triggers would show as disabled.

- Fix `\copy` to no longer require a space between `stdin` and a semicolon (Etsuro Fujita)
- Output the row count at the end of `\copy`, just like `COPY` already did (Kumar Rajeev Rastogi)
- Fix `\conninfo` to display the server's IP address for connections using `hostaddr` (Fujii Masao)

Previously `\conninfo` could not display the server's IP address in such cases.

- Show the SSL protocol version in `\conninfo` (Marko Kreen)
- Add tab completion for `\pset` (Pavel Stehule)
- Allow `\pset` with no arguments to show all settings (Gilles Darold)
- Make `\s` display the name of the history file it wrote without converting it to an absolute path (Tom Lane)

The code previously attempted to convert a relative file name to an absolute path for display, but frequently got it wrong.

- Allow `pg_restore` options `-I`, `-P`, `-T` and `-n` to be specified multiple times (Heikki Linnakangas)

This allows multiple objects to be restored in one operation.

- Optionally add `IF EXISTS` clauses to the `DROP` commands emitted when removing old objects during a restore (Pavel Stehule)

This change prevents unnecessary errors when removing old objects. The new `--if-exists` option for `pg_dump`, `pg_dumpall`, and `pg_restore` is only available when `--clean` is also specified.

- Add `pg_basebackup` option `--xlogdir` to specify the `pg_xlog` directory location (Haribabu Kommi)
- Allow `pg_basebackup` to relocate tablespaces in the backup copy (Steeve Lennmark)

This is particularly useful for using `pg_basebackup` on the same machine as the primary.

- Allow network-stream base backups to be throttled (Antonin Houska)

This can be controlled with the `pg_basebackup --max-rate` parameter.

### E.60.3.11. Source Code

- Improve the way tuples are frozen to preserve forensic information (Robert Haas, Andres Freund)

This change removes the main objection to freezing tuples as soon as possible. Code that inspects tuple flag bits will need to be modified.

- No longer require function prototypes for functions marked with the `PG_FUNCTION_INFO_V1` macro (Peter Eisentraut)

This change eliminates the need to write boilerplate prototypes. Note that the `PG_FUNCTION_INFO_V1` macro must appear before the corresponding function definition to avoid compiler warnings.

- Remove `SnapshotNow` and `HeapTupleSatisfiesNow()` (Robert Haas)

All existing uses have been switched to more appropriate snapshot types. Catalog scans now use MVCC snapshots.

- Add an API to allow memory allocations over one gigabyte (Noah Misch)
- Add `psprintf()` to simplify memory allocation during string composition (Peter Eisentraut, Tom Lane)
- Support `printf()` size modifier `z` to print `size_t` values (Andres Freund)
- Change API of `appendStringInfoVA()` to better use `vsnprintf()` (David Rowley, Tom Lane)
- Allow new types of external toast datums to be created (Andres Freund)
- Add single-reader, single-writer, lightweight shared message queue (Robert Haas)

- Improve spinlock speed on x86\_64 CPUs (Heikki Linnakangas)
- Remove spinlock support for unsupported platforms SINIX, Sun3, and NS32K (Robert Haas)
- Remove IRIX port (Robert Haas)
- Reduce the number of semaphores required by `--disable-spinlocks` builds (Robert Haas)
- Rewrite `duplicate_oids` Unix shell script in Perl (Andrew Dunstan)
- Add Test Anything Protocol (TAP) tests for client programs (Peter Eisentraut)

Currently, these tests are run by `make check-world` only if the `--enable-tap-tests` option was given to configure. This might become the default behavior in some future release.

- Add `make` targets `check-tests` and `installcheck-tests`, which allow selection of individual tests to be run (Andrew Dunstan)
- Remove `maintainer-check` `makefile` rule (Peter Eisentraut)

The default build rules now include all the formerly-optional tests.

- Improve support for `VPATH` builds of PGXS modules (Cédric Villemain, Andrew Dunstan, Peter Eisentraut)
- Upgrade to Autoconf 2.69 (Peter Eisentraut)
- Add a configure flag that appends custom text to the `PG_VERSION` string (Oskari Saarenmaa)

This is useful for packagers building custom binaries.

- Improve DocBook XML validity (Peter Eisentraut)
- Fix various minor security and sanity issues reported by the Coverity scanner (Stephen Frost)
- Improve detection of invalid memory usage when testing PostgreSQL with Valgrind (Noah Misch)
- Improve sample Emacs configuration file `emacs.samples` (Peter Eisentraut)

Also add `.dir-locals.el` to the top of the source tree.

- Allow `pgindent` to accept a command-line list of typedefs (Bruce Momjian)
- Make `pgindent` smarter about blank lines around preprocessor conditionals (Bruce Momjian)
- Avoid most uses of `dlltool` in Cygwin and Mingw builds (Marco Atzeri, Hiroshi Inoue)
- Support client-only installs in MSVC (Windows) builds (MauMau)

### **E.60.3.12. Additional Modules**

- Add `pg_prewarm` extension to preload relation data into the shared buffer cache at server start (Robert Haas)

This allows reaching full operating performance more quickly.

- Add UUID random number generator `gen_random_uuid()` to `pgcrypto` (Oskari Saarenmaa)

This allows creation of version 4 UUIDs without requiring installation of `uuid-oss`.

- Allow `uuid-oss` to work with the BSD or `e2fsprogs` UUID libraries, not only the OSSP UUID library (Matteo Beccati)

This improves the `uuid-oss` module's portability since it no longer has to have the increasingly-obsolete OSSP library. The module's name is now rather a misnomer, but we won't change it.

- Add option to `auto_explain` to include trigger execution time (Horiguchi Kyotaro)
- Fix `pgstattuple` to not report rows from uncommitted transactions as dead (Robert Haas)

- Make `pgstattuple` functions use `regclass`-type arguments (Satoshi Nagayasu)

While `text`-type arguments are still supported, they may be removed in a future major release.

- Improve consistency of `pgrowlocks` output to honor snapshot rules more consistently (Robert Haas)
- Improve `pg_trgm`'s choice of trigrams for indexed regular expression searches (Alexander Korotkov)

This change discourages use of trigrams containing whitespace, which are usually less selective.

- Allow `pg_xlogdump` to report a live log stream with `--follow` (Heikki Linnakangas)
- Store cube data more compactly (Stas Kelvich)

Existing data must be dumped/restored to use the new format. The old format can still be read.

- Reduce vacuumlo client-side memory usage by using a cursor (Andrew Dunstan)
- Dramatically reduce memory consumption in `pg_upgrade` (Bruce Momjian)
- Pass `pg_upgrade`'s user name (`-U`) option to generated analyze scripts (Bruce Momjian)

- Remove line length limit for `pgbench` scripts (Sawada Masahiko)

The previous line limit was `BUFSIZ`.

- Add long option names to `pgbench` (Fabien Coelho)
- Add `pgbench` option `--rate` to control the transaction rate (Fabien Coelho)
- Add `pgbench` option `--progress` to print periodic progress reports (Fabien Coelho)

- Make `pg_stat_statements` use a file, rather than shared memory, for query text storage (Peter Geoghegan)

This removes the previous limitation on query text length, and allows a higher number of unique statements to be tracked by default.

- Allow reporting of `pg_stat_statements`'s internal query hash identifier (Daniel Farina, Sameer Thakur, Peter Geoghegan)
- Add the ability to retrieve all `pg_stat_statements` information except the query text (Peter Geoghegan)

This allows monitoring tools to fetch query text only for just-created entries, improving performance during repeated querying of the statistics.

- Make `pg_stat_statements` ignore `DEALLOCATE` commands (Fabien Coelho)

It already ignored `PREPARE`, as well as planning time in general, so this seems more consistent.

- Save the statistics file into `$PGDATA/pg_stat` at server shutdown, rather than `$PGDATA/global` (Fujii Masao)

## E.61. Release 9.3.20

**Release date:** 2017-11-09

This release contains a variety of fixes from 9.3.19. For information about new features in the 9.3 major release, see Section E.81.

### E.61.1. Migration to Version 9.3.20

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.18, see Section E.63.

## E.61.2. Changes

- Fix crash due to rowtype mismatch in `json{b}_populate_recordset()` (Michael Paquier, Tom Lane)

These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn't, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range's subtype has hash support. This does not affect any of the built-in range types, since they're all hashable anyway.

- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Correctly restore the `umask` setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)
- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)
- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)
- Fix libpq to not require user's home directory to exist (Tom Lane)

In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- Fix libpq to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)
- Fix ecpg's handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)

- Make ecpglib's Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

## E.62. Release 9.3.19

**Release date:** 2017-08-31

This release contains a small number of fixes from 9.3.18. For information about new features in the 9.3 major release, see Section E.81.

### E.62.1. Migration to Version 9.3.19

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.18, see Section E.63.

### E.62.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in `psql`:

```
SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
    SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
           CAST(grantee.rolname AS sql_identifier) AS grantee,
           CAST(current_database() AS sql_identifier) AS table_catalog,
           CAST(nc.nspname AS sql_identifier) AS table_schema,
           CAST(c.relname AS sql_identifier) AS table_name,
           CAST(c.prptype AS character_data) AS privilege_type,
           CAST(
               CASE WHEN
                   -- object owner always has grant options
                   pg_has_role(grantee.oid, c.relowner, 'USAGE')
                   OR c.grantable
                   THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
           CAST(CASE WHEN c.prptype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no)
AS with_hierarchy

FROM (
    SELECT oid, relname, relnamespace, relkind, relowner,
           (aclxplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
    ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee,
           prptype, grantable),
       pg_namespace nc,
       pg_authid u_grantor,
       (
```

```

SELECT oid, rolname FROM pg_authid
UNION ALL
SELECT 0::oid, 'PUBLIC'
) AS grantee (oid, rolname)

WHERE c.relnamespace = nc.oid
AND c.relkind IN ('r', 'v', 'f')
AND c.grantee = grantee.oid
AND c.grantor = u_grantor.oid
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE',
'REFERENCES', 'TRIGGER')
AND (pg_has_role(u_grantor.oid, 'USAGE')
OR pg_has_role(grantee.oid, 'USAGE')
OR grantee.rolname = 'PUBLIC');

```

This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)

This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Fix crash in `pg_restore` when using parallel mode and using a list file to select a subset of items to restore (Fabrício de Royes Mello)
- Change `ecpg`'s parser to allow RETURNING clauses without attached C variables (Michael Meskes)

This allows `ecpg` programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T` is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.

## E.63. Release 9.3.18

**Release date:** 2017-08-10

This release contains a variety of fixes from 9.3.17. For information about new features in the 9.3 major release, see Section E.81.

### E.63.1. Migration to Version 9.3.18

A dump/restore is not required for those running 9.3.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.16, see Section E.65.

## E.63.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you'll still need a restart.)
2. In *each* database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;
CREATE OR REPLACE VIEW pg_user_mappings AS
SELECT
    U.oid        AS umid,
    S.oid        AS srvid,
    S.srvname    AS srvname,
    U.umuser     AS umuser,
    CASE WHEN U.umuser = 0 THEN
        'public'
    ELSE
        A.rolname
    END AS username,
    CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
              AND (pg_has_role(S.srvowner, 'USAGE')
                  OR has_server_privilege(S.oid, 'USAGE')))
        OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
        OR (SELECT rolsuper FROM pg_authid WHERE rolname =
current_user)
    THEN U.umoptions
    ELSE NULL END AS umoptions
FROM pg_user_mapping U
    LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
    pg_foreign_server S ON (U.umserver = S.oid);
```

3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing `template0`, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

libpq ignores empty password specifications, and does not transmit them to the server. So, if a user's password has been set to the empty string, it's impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Fix concurrent locking of tuple update chains (Álvaro Herrera)

If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

- Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)
- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
- Prevent sending SSL session tickets to clients (Tom Lane)

This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting tcp\_keepalives\_idle on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector's receive buffer size is at least 100KB (Tom Lane)

This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG\_SWITCH WAL record (Andres Freund)
- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Allow window functions to be used in sub-SELECTs that are within the arguments of an aggregate function (Tom Lane)
- Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)

Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.

- Ensure that `ALTER USER ... SET` accepts all the syntax variants that `ALTER ROLE ... SET` does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function's argument or return type from `opaque` to the correct type (Heikki Linnakangas)

`CREATE TYPE` updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent `DROP TYPE` to leave broken function definitions behind.

- Reduce memory usage when `ANALYZE` processes a `tsvector` column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing `money` values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as `regprocedurein()` (Tom Lane)

Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant `#define` symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In `libpq`, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)

Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In `psql`, fix failure when `COPY FROM STDIN` is ended with a keyboard EOF signal and then another `COPY FROM STDIN` is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix `pg_dump` and `pg_restore` to emit `REFRESH MATERIALIZED VIEW` commands last (Tom Lane)

This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Fix `pg_dump` with the `--clean` option to drop event triggers as expected (Tom Lane)

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix `pg_dump` to not emit invalid SQL for an empty operator class (Daniel Gustafsson)
- Fix `pg_dump` output to stdout on Windows (Kuntal Ghosh)

A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.

- Fix dumping of outer joins with empty constraints, such as the result of a `NATURAL LEFT JOIN` with no common columns (Tom Lane)
- Fix dumping of function expressions in the `FROM` clause in cases where the expression does not parse into something that looks like a function call (Tom Lane)

- Fix `pg_basebackup` output to stdout on Windows (Haribabu Kommi)

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

- In `postgres_fdw`, re-establish connections to remote servers after `ALTER SERVER` or `ALTER USER MAPPING` commands (Kyotaro Horiguchi)

This ensures that option changes affecting connection parameters will be applied promptly.

- In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)

This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.

- Always use `-fPIC`, not `-fpic`, when building shared libraries with `gcc` (Tom Lane)

This supports larger extension libraries on platforms where it makes a difference.

- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the `openssl` library is not within a `vc` subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for `libxml2` header files (Andrew Dunstan)

This fixes a former need to move things around in standard Windows installations of `libxml2`.

- In MSVC builds, recognize a Tcl library that is named `tc186.lib` (Noah Misch)

## E.64. Release 9.3.17

**Release date:** 2017-05-11

This release contains a variety of fixes from 9.3.16. For information about new features in the 9.3 major release, see Section E.81.

### E.64.1. Migration to Version 9.3.17

A dump/restore is not required for those running 9.3.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.16, see Section E.65.

### E.64.2. Changes

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.63.

- Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator's implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

- Restore libpq's recognition of the `PGREQUIRESSL` environment variable (Daniel Gustafsson)

Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than `PGSSLMODE`, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

- Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

- Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)

- Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)
- Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn't accessible, so that no logging happens at all.

- Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)
- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -l`'s purposes.

- Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)

Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in `contrib/adminpack`'s `pg_file_write()` function (Noah Misch)

Notably, it failed to detect errors reported by `fclose()`.

- In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix `contrib/pg_trgm`'s extraction of trigrams from regular expressions (Tom Lane)

In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In `contrib/postgres_fdw`, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)

Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.

- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)

This is a back-patch of work previously done in newer branches; it's needed since many platforms are adopting newer OpenSSL versions.

- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release `tzcode2017b` (Tom Lane)

This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the `posixrules` file in the `timezone` directory tree. This resulted in the `timezone` code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the `US/Eastern` zone. If you don't want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

## E.65. Release 9.3.16

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.3.15. For information about new features in the 9.3 major release, see Section E.81.

### E.65.1. Migration to Version 9.3.16

A dump/restore is not required for those running 9.3.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.3.15, see Section E.66.

### E.65.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

Previously, this was skipped when `wal_level = minimal`, but actually it's necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)
- Ensure that hot standby feedback works correctly when it's enabled at standby server start (Ants Aasma, Craig Ringer)
- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)
- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

This avoids “could not find trigger *NNN*” or “relation *NNN* has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)

The OID column should be treated the same as regular user columns in this case, but it wasn't, leading to odd behavior in later inheritance changes.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)

The wrong catalog OID was reported to extensions such as logical decoding.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)

This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)

This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don't share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)

Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)
- Fix performance problems in `ts_rewrite()` (Tom Lane)
- Fix `ts_rewrite()`'s handling of nested NOT operators (Tom Lane)

- Fix `array_fill()` to handle empty arrays properly (Tom Lane)
- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)

The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)

This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Avoid discarding `interval-to-interval` casts that aren't really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)
- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)

This matches the (previously undocumented) behavior of PL/Tcl's `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn't a real column named that.

- Allow DOS-style line endings in `~/.pgpass` files, even on Unix (Vik Fearing)

This change simplifies use of the same password file across Unix and Windows machines.

- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix `psql`'s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)

Previously, such a setting caused output intended for the pager to vanish entirely.

- Improve `contrib/dblink`'s reporting of low-level `libpq` errors, such as out-of-memory (Joe Conway)
- Teach `contrib/dblink` to ignore irrelevant server options when it uses a `contrib/postgres_fdw` foreign server as the source of connection options (Corey Huinker)

Previously, if the foreign server object had options that were not also `libpq` connection options, an error occurred.

- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release `tzcode2016j` (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn't support hard links.

- Update time zone data files to `tzdata` release 2016j for DST law changes in northern Cyprus (adding a new zone `Asia/Famagusta`), Russia (adding a new zone `Europe/Saratov`), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

## E.66. Release 9.3.15

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.3.14. For information about new features in the 9.3 major release, see Section E.81.

### E.66.1. Migration to Version 9.3.15

A dump/restore is not required for those running 9.3.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.3.9, see Section E.72.

### E.66.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block *xxx*: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at [https://wiki.postgresql.org/wiki/Free\\_Space\\_Map\\_Problems](https://wiki.postgresql.org/wiki/Free_Space_Map_Problems).

- Fix `SELECT FOR UPDATE/SHARE` to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)

In 9.5 and later, the `SELECT` would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gieth)

The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix `EXPLAIN` to emit valid XML when `track_io_timing` is on (Markus Winand)

Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- Suppress printing of zeroes for unmeasured times in `EXPLAIN` (Maksim Milyutin)

Certain option combinations resulted in printing zero values for times that actually aren't ever measured in that combination. Our general policy in `EXPLAIN` is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when `VACUUM` is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing `VACUUM` to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- Remove artificial restrictions on the values accepted by `numeric_in()` and `numeric_recv()` (Tom Lane)

We allow numeric values up to the limit of the storage format (more than `1e100000`), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
- Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)

This can't do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn't designed with this situation in mind.

- Don't try to share SSL contexts across multiple connections in `libpq` (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in `libpq` (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

- Make `ecpg's --help` and `--version` options work consistently with our other executables (Haribabu Kommi)
- In `pg_dump`, never dump range constructor functions (Tom Lane)

This oversight led to `pg_upgrade` failures with extensions containing range types, due to duplicate creation of the constructor functions.

- In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Hagan-der)

This allows for a possible delay in the server's creation of the next segment.

- Fix `pg_xlogdump` to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
- Fix `contrib/intarray/bench/bench.pl` to print the results of the `EXPLAIN` it does when given the `-e` option (Daniel Gustafsson)
- Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in `tzdata` release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbrevs` view to fail altogether.

- Update time zone data files to `tzdata` release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, `AMT` is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the `Default` abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

## E.67. Release 9.3.14

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.3.13. For information about new features in the 9.3 major release, see Section E.81.

### E.67.1. Migration to Version 9.3.14

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.72.

### E.67.2. Changes

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function's body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs' handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in `vacuumdb` and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a `conninfo` string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in `psql`'s `\connect` and `\password` commands to match the documentation.

Introduce a new `-reuse-previous` option in `psql`'s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a `conninfo` string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

`pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that `IS NULL` should return `TRUE` for a row of all null values (thus `ROW(NULL, NULL) IS NULL` yields `TRUE`), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL, NULL)) IS NULL` yields `FALSE`). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing `TRUE` in both cases), and `contrib/postgres_fdw` could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)
- Prevent crash in `close_ps()` (the `point ## lseg` operator) for NaN input coordinates (Tom Lane)

Make it return `NULL` instead of crashing.

- Avoid possible crash in `pg_get_expr()` when inconsistent values are passed to it (Michael Paquier, Thomas Munro)
- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)

This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn't exist yet.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

Previously, these cases locked the target tuple (by setting its `XMAX`) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Fix hint bit update during WAL replay of row locking operations (Andres Freund)

The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.

- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)
- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)
- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)

The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)
- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

Some cases in `VACUUM` unnecessarily caused an `XID` to be assigned to the current transaction. Normally this is negligible, but if one is up against the `XID` wraparound limit, consuming more `XIDs` during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during `VACUUM FREEZE` (Simon Riggs, Álvaro Herrera)

`VACUUM FREEZE` on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- Prevent possible failure when vacuuming multixact IDs in an installation that has been `pg_upgrade`'d from pre-9.3 (Andrew Gierth, Álvaro Herrera)

The usual symptom of this bug is errors like “MultiXactId *NNN* has not been created yet -- apparent wraparound”.

- When a manual `ANALYZE` specifies a column list, don't reset the table's `changes_since_analyze` counter (Tom Lane)

If we're only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix `ANALYZE`'s overestimation of `n_distinct` for a unique or nearly-unique column with many null entries (Tom Lane)

The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

Normally this isn't much of a problem because the vacuum doesn't take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
- Fix `contrib/btree_gin` to handle the smallest possible `bigint` value correctly (Peter Eisentraut)
- Teach `libpq` to correctly decode server version from future servers (Peter Eisentraut)

It's planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that `PQserverVersion()` returns the correct value for such cases.

- Fix `ecpg`'s code for `unsigned long long` array elements (Michael Meskes)
- In `pg_dump` with both `-c` and `-C` options, avoid emitting an unwanted `CREATE SCHEMA public` command (David Johnston, Tom Lane)
- Improve handling of SIGTERM/control-C in parallel `pg_dump` and `pg_restore` (Tom Lane)

Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a `CREATE INDEX`.

- Fix error reporting in parallel `pg_dump` and `pg_restore` (Tom Lane)

Previously, errors reported by `pg_dump` or `pg_restore` worker processes might never make it to the user's console, because the messages went through the master process, and there were various deadlock scenarios that would prevent the master process from passing on the messages. Instead, just print everything to `stderr`. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.

- Ensure that parallel `pg_dump` or `pg_restore` on Windows will shut down properly after an error (Kyotaro Horiguchi)

Previously, it would report the error, but then just sit until manually stopped by the user.

- Make `pg_dump` behave better when built without `zlib` support (Kyotaro Horiguchi)

It didn't work right for parallel dumps, and emitted some rather pointless warnings in other cases.

- Make `pg_basebackup` accept `-z 0` as specifying no compression (Fujii Masao)
- Fix `makefiles`' rule for building AIX shared libraries to be safe for parallel `make` (Noah Misch)

- Fix TAP tests and MSVC scripts to work when build directory's path name contains spaces (Michael Paquier, Kyotaro Horiguchi)
- Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)

On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.

- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA's tzcode release 2016c (Tom Lane)

This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

## E.68. Release 9.3.13

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.3.12. For information about new features in the 9.3 major release, see Section E.81.

### E.68.1. Migration to Version 9.3.13

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.72.

### E.68.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it's clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It's possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any  $N$ -way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)
- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

Given a three-or-more-way equivalence class of variables, such as  $X.X = Y.Y = Z.Z$ , it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn't satisfy the `WHERE` clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix possible misbehavior of `TH`, `th`, and `Y`, `YYY` format codes in `to_timestamp()` (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the `array` argument of a `value operator ANY (array)` construct is a sub-SELECT (Tom Lane)
- Make `pg_regress` use a startup timeout from the `PGCLTIMEOUT` environment variable, if that's set (Tom Lane)

This is for consistency with a behavior recently added to `pg_ctl`; it eases automated testing on slow machines.

- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.

- Fix `pg_upgrade` to not fail when new-cluster TOAST rules differ from old (Tom Lane)

`pg_upgrade` had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can't get along fine without a TOAST table if that was okay according to the old version's rules.

- Back-port 9.4-era memory-barrier code changes into 9.2 and 9.3 (Tom Lane)

These changes were not originally needed in pre-9.4 branches, but we recently back-patched a fix that expected the barrier code to work properly. Only IA64 (when using `icc`), HPPA, and Alpha platforms are affected.

- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks` (Tom Lane)
- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)
- Avoid possibly-unsafe use of Windows' `FormatMessage()` function (Christian Ullrich)

Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

## E.69. Release 9.3.12

**Release date:** 2016-03-31

This release contains a variety of fixes from 9.3.11. For information about new features in the 9.3 major release, see Section E.81.

### E.69.1. Migration to Version 9.3.12

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.72.

### E.69.2. Changes

- Fix incorrect handling of NULL index entries in indexed `ROW()` comparisons (Tom Lane)

An index search using a row comparison such as `ROW(a, b) > ROW('x', 'y')` would stop upon reaching a NULL entry in the `b` column, ignoring the fact that there might be non-NULL `b` values associated with later values of `a`.

- Avoid unlikely data-loss scenarios due to renaming files without adequate `fsync()` calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)
- Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
- Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
- Fix parsing of affix files for `ispell` dictionaries (Tom Lane)

The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example `ı` in Turkish UTF8 locales.

- Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)

This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)

This is a workaround for a bug in Visual Studio 2013's runtime library, which Microsoft have stated they will not fix in that version.

- Fix `psql`'s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)
- Fix `psql`'s tab completion for `SECURITY LABEL` (Tom Lane)

Pressing TAB after `SECURITY LABEL` might cause a crash or offering of inappropriate keywords.

- Make `pg_ctl` accept a wait timeout from the `PGCTLTIMEOUT` environment variable, if none is specified on the command line (Noah Misch)

This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

- Fix incorrect test for Windows service status in `pg_ctl` (Manuel Mathar)

The previous set of minor releases attempted to fix `pg_ctl` to properly determine whether to send log messages to Window's Event Log, but got the test backwards.

- Fix `pgbench` to correctly handle the combination of `-C` and `-M prepared` options (Tom Lane)
- In `pg_upgrade`, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)

Blind application of the script in such cases would result in loss of the new data directory.

- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren't valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by `contrib/pgstattuple`'s `pgstatindex()` function (Tom Lane)
- Remove dependency on `psed` in MSVC builds, since it's no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to `tzdata` release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

## E.70. Release 9.3.11

**Release date:** 2016-02-11

This release contains a variety of fixes from 9.3.10. For information about new features in the 9.3 major release, see Section E.81.

## E.70.1. Migration to Version 9.3.11

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.72.

## E.70.2. Changes

- Fix infinite loops and buffer-overflow problems in regular expressions (Tom Lane)

Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- Perform an immediate shutdown if the `postmaster.pid` file is removed (Tom Lane)

The postmaster now checks every minute or so that `postmaster.pid` is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes `postmaster.pid` and then starts a new postmaster.

- In `SERIALIZABLE` transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)
- Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)

Even though the relation's data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)
- Ensure walsender slots are fully re-initialized when being re-used (Magnus Hagander)
- Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)
- Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)
- Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)
- Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)
- Fix possible crash after doing query rewrite for an updatable view (Stephen Frost)
- Fix planner's handling of `LATERAL` references (Tom Lane)

This fixes some corner cases that led to “failed to build any N-way joins” or “could not devise a query plan” planner failures.

- Add more defenses against bad planner cost estimates for GIN index scans when the index's internal statistics are very out-of-date (Tom Lane)
- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
- Speed up generation of unique table aliases in `EXPLAIN` and rule dumping, and ensure that generated aliases do not exceed `NAMEDATALEN` (Tom Lane)
- Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)
- Fix possible internal overflow in numeric division (Dean Rasheed)
- Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)

Lookahead constraints aren't allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

- Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)
- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)

The code added for CVE-2007-4772 was both incomplete, in that it didn't handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

- Improve memory-usage accounting in regular-expression compiler (Tom Lane)

This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

- Improve performance of regular-expression compiler (Tom Lane)
- Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)

Previously, `%h/%r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don't need it (Tom Lane, Amit Kapila)

This oversight resulted in failure to recover from crashes whenever `logging_collector` is turned on.

- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

It's not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)
- In `psql`, ensure that `libreadline`'s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

Previously, `libreadline` did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

- Fix `psql`'s `\det` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)
- Avoid possible crash in `psql`'s `\c` command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)
- In `pg_ctl start -w`, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, `pg_ctl` relied on an assumption that the new postmaster would always create `postmaster.pid` within five seconds. But that can fail on heavily-loaded systems, causing `pg_ctl` to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a `pg_ctl start -w done` immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In `pg_ctl start -w`, don't attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `:::`, because it would try to use that value verbatim as the address to connect to, which doesn't work. Instead assume that `127.0.0.1` or `:::1`, respectively, is the right thing to use.

- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)
- In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of `tar` support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in `pg_dump`'s processing of extension member objects (Tom Lane)
- Make `pg_dump` mark a view's triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)
- Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

A reloption value that isn't a simple identifier or number could lead to dump/reload failures due to syntax errors in `CREATE` statements issued by `pg_dump`. This is not an issue with any reloption currently supported by core PostgreSQL, but extensions could allow relocations that cause the problem.

- Avoid repeated password prompts during parallel `pg_dump` (Zeus Kronion)
- Fix `pg_upgrade`'s file-copying code to handle errors properly on Windows (Bruce Momjian)
- Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)
- Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Ioseph Kim)
- Avoid dump/reload problems when using both `plpython2` and `plpython3` (Tom Lane)

In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of `libpython` cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
- Fix premature clearing of `libpq`'s input buffer when socket EOF is seen (Tom Lane)

This mistake caused `libpq` to sometimes not report the backend's final error message before reporting "server closed the connection unexpectedly".

- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

- Improve `libpq`'s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linakangas)
- Fix order of arguments in `ecpg-generated typedef` statements (Michael Meskes)
- Use `%g` not `%f` format in `ecpg's PGTYPEsnnumeric_from_double()` (Tom Lane)
- Fix `ecpg-supplied` header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)

Such a comment is rejected by `ecpg`. It's not yet clear whether `ecpg` itself should be changed.

- Fix `hstore_to_json_loose()`'s test for whether an `hstore` value can be converted to a JSON number (Tom Lane)

Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.

- Ensure that `contrib/pgcrypto`'s `crypt()` function can be interrupted by query cancel (Andreas Karlsson)
- Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)

Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.

- Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)

This avoids possible bitwise differences in the produced executable files from one build to the next.

- Install our `missing` script where PGXS builds can find it (Jim Nasby)

This allows sane behavior in a PGXS build done on a machine where build tools such as `bison` are missing.

- Ensure that `dynloader.h` is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Add variant regression test expected-output file to match behavior of current `libxml2` (Tom Lane)

The fix for `libxml2`'s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we'll probably have to live with it for some time, so work around it.

- Update time zone data files to `tzdata` release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

## E.71. Release 9.3.10

**Release date:** 2015-10-08

This release contains a variety of fixes from 9.3.9. For information about new features in the 9.3 major release, see Section E.81.

### E.71.1. Migration to Version 9.3.10

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.9, see Section E.72.

### E.71.2. Changes

- Guard against stack overflows in `json` parsing (Oskari Saarenmaa)

If an application constructs PostgreSQL `json` or `jsonb` values from arbitrary user input, the application's users can reliably crash the PostgreSQL server, causing momentary denial of service. (CVE-2015-5289)

- Fix `contrib/pgcrypto` to detect and report too-short `crypt()` salts (Josh Kupershmidt)

Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)

A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Ensure all relations referred to by an updatable view are properly locked during an update statement (Dean Rasheed)
- Fix insertion of relations into the relation cache “init file” (Tom Lane)

An oversight in a patch in the most recent minor releases caused `pg_trigger_tgrelid_tgname_index` to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid  $O(N^2)$  behavior when inserting many tuples into a SPI query result (Neil Conway)
- Improve `LISTEN` startup time when there are many unread notifications (Matt Newell)
- Fix performance problem when a session alters large numbers of foreign key constraints (Jan Wieck, Tom Lane)

This was seen primarily when restoring `pg_dump` output for databases with many thousands of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

- Lower the minimum values of the `*_freeze_max_age` parameters (Andres Freund)

This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)
- Avoid logging complaints when a parameter that can only be set at server start appears multiple times in `postgresql.conf`, and fix counting of line numbers after an `include_dir` directive (Tom Lane)
- Fix rare internal overflow in multiplication of `numeric` values (Dean Rasheed)
- Guard against hard-to-reach stack overflows involving record types, range types, `json`, `jsonb`, `tsquery`, `ltxtquery` and `query_int` (Noah Misch)
- Fix handling of `DOW` and `DOY` in datetime input (Greg Stark)

These tokens aren't meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, `SIMILAR TO`, and `LIKE` matching (Tom Lane)

Suitable search patterns and a low stack depth limit could lead to stack-overflow crashes.

- Fix potential infinite loop in regular expression execution (Tom Lane)

A search pattern that can apparently match a zero-length string, but actually doesn't match because of a back reference, could lead to an infinite loop.

- In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)

- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)
- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)
- Fix very-low-probability stack overrun in `qsort` (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)

These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan's variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.

- Improve planner's performance for `UPDATE/DELETE` on large inheritance sets (Tom Lane, Dean Rasheed)
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)

This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.

- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the `postmaster.pid` file (Tom Lane)

This avoids race-condition failures if an external script attempts to start a new postmaster as soon as `pg_ctl stop` returns.

- Fix postmaster's handling of a startup-process crash during crash recovery (Tom Lane)

If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we'd try to launch a new startup process, which typically would just crash again, leading to an infinite loop.

- Make emergency autovacuuming for multixact wraparound more robust (Andres Freund)
- Do not print a `WARNING` when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index's pending-insertions list is interruptable by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)

Such a page might be left behind after a crash.

- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)

`VACUUM` attempted to recycle such pages, but did so in a way that wasn't crash-safe.

- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)
- Fix misreporting of `CONTINUE` and `MOVE` statement types in PL/pgSQL's error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)

- Fix PL/Python crash when returning the string representation of a `record` result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of `malloc()` calls (Michael Paquier, Álvaro Herrera)
- In `contrib/isn`, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)

EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

- Improve `contrib/postgres_fdw`'s handling of collation-related decisions (Tom Lane)

The main user-visible effect is expected to be that comparisons involving `varchar` columns will be sent to the remote server for execution in more cases than before.

- Improve `libpq`'s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in `ecpg` (Michael Paquier)
- Fix `psql`'s code for locale-aware formatting of numeric output (Tom Lane)

The formatting code invoked by `\pset numericlocale on` did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the `money` data type.

- Prevent crash in `psql`'s `\c` command when there is no current connection (Noah Misch)
- Make `pg_dump` handle inherited `NOT VALID` check constraints correctly (Tom Lane)
- Fix selection of default `zlib` compression level in `pg_dump`'s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a `pg_dump` run with `tar-format` output are not world-readable (Michael Paquier)
- Fix `pg_dump` and `pg_upgrade` to support cases where the `postgres` or `template1` database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix `pg_dump` to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)

When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, `pg_dump` would produce `GRANT/REVOKE` commands that revoked the owner's grantable privileges and instead granted all privileges to `PUBLIC`. Since the privileges involved are just `USAGE` and `EXECUTE`, this isn't a security problem, but it's certainly a surprising representation of the older systems' behavior. Fix it to leave the default privilege state alone in these cases.

- Fix `pg_dump` to dump shell types (Tom Lane)

Shell types (that is, not-yet-fully-defined types) aren't useful for much, but nonetheless `pg_dump` should dump them.

- Fix assorted minor memory leaks in `pg_dump` and other client-side programs (Michael Paquier)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX's native assembler (Tom Lane)

Building with `gcc` didn't work if `gcc` had been configured to use the native assembler, which is becoming more common.

- On AIX, test the `-qlonglong` compiler option rather than just assuming it's safe to use (Noah Misch)
- On AIX, use `-Wl,-brtllib` link option to allow symbols to be resolved at runtime (Noah Misch)

Perl relies on this ability in 5.8.0 and later.

- Avoid use of inline functions when compiling with 32-bit `xc`, due to compiler bugs (Noah Misch)

- Use `librt` for `sched_yield()` when necessary, which it is on some Solaris versions (Oskari Saaremaa)
- Fix Windows `install.bat` script to handle target directory names that contain spaces (Heikki Linakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named `VERSION_NUM` (Michael Paquier)
- Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name `America/Fort_Nelson` for the Canadian Northern Rockies.

## E.72. Release 9.3.9

**Release date:** 2015-06-12

This release contains a small number of fixes from 9.3.8. For information about new features in the 9.3 major release, see Section E.81.

### E.72.1. Migration to Version 9.3.9

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading an installation that was previously upgraded using a `pg_upgrade` version between 9.3.0 and 9.3.4 inclusive, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.3.7, see Section E.74.

### E.72.2. Changes

- Fix possible failure to recover from an inconsistent database state (Robert Haas)

Recent PostgreSQL releases introduced mechanisms to protect against multixact wraparound, but some of that code did not account for the possibility that it would need to run during crash recovery, when the database may not be in a consistent state. This could result in failure to restart after a crash, or failure to start up a secondary server. The lingering effects of a previously-fixed bug in `pg_upgrade` could also cause such a failure, in installations that had used `pg_upgrade` versions between 9.3.0 and 9.3.4.

The `pg_upgrade` bug in question was that it would set `oldestMultiXid` to 1 in `pg_control` even if the true value should be higher. With the fixes introduced in this release, such a situation will result in immediate emergency autovacuuming until a correct `oldestMultiXid` value can be determined. If that would pose a hardship, users can avoid it by doing manual vacuuming *before* upgrading to this release. In detail:

1. Check whether `pg_control` reports “Latest checkpoint's oldestMultiXid” to be 1. If not, there's nothing to do.
  2. Look in `PGDATA/pg_multixact/offsets` to see if there's a file named `0000`. If there is, there's nothing to do.
  3. Otherwise, for each table that has `pg_class.relminmxid` equal to 1, `VACUUM` that table with both `vacuum_multixact_freeze_min_age` and `vacuum_multixact_freeze_table_age` set to zero. (You can use the vacuum cost delay parameters described in Section 20.4.4 to reduce the performance consequences for concurrent sessions.) You must use PostgreSQL 9.3.5 or later to perform this step.
- Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a `VACUUM FULL` on a system catalog might fail to update the “init file” that's used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it's so hard to trigger that no reproducible case had been seen until recently.

- Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE` (Tom Lane)

A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

- Improve planner's cost estimates for semi-joins and anti-joins with inner indexscans (Tom Lane, Tomas Vondra)

This type of plan is quite cheap when all the join clauses are used as index scan conditions, even if the inner scan would nominally fetch many rows, because the executor will stop after obtaining one row. The planner only partially accounted for that effect, and would therefore overestimate the cost, leading it to possibly choose some other much less efficient plan type.

## E.73. Release 9.3.8

**Release date:** 2015-06-04

This release contains a small number of fixes from 9.3.7. For information about new features in the 9.3 major release, see Section E.81.

### E.73.1. Migration to Version 9.3.8

A dump/restore is not required for those running 9.3.X.

However, if you are upgrading from a version earlier than 9.3.7, see Section E.74.

### E.73.2. Changes

- Avoid failures while `fsync`'ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)

In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

Also apply the same rules in `initdb --sync-only`. This case is less critical but it should act similarly.

- Fix `pg_get_functiondef()` to show functions' `LEAKPROOF` property, if set (Jeevan Chalke)
- Remove configure's check prohibiting linking to a threaded libpython on OpenBSD (Tom Lane)

The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

- Allow libpq to use TLS protocol versions beyond v1 (Noah Misch)

For a long time, libpq was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

## E.74. Release 9.3.7

**Release date:** 2015-05-22

This release contains a variety of fixes from 9.3.6. For information about new features in the 9.3 major release, see Section E.81.

### E.74.1. Migration to Version 9.3.7

A dump/restore is not required for those running 9.3.X.

However, if you use `contrib/citext`'s `regexp_matches()` functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.3.6, see Section E.75.

### E.74.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)

Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn't been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

It remains possible that some calls of the `*printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from other systems. While it's unknown whether `pgcrypto`'s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Protect against wraparound of multixact member IDs (Álvaro Herrera, Robert Haas, Thomas Munro)

Under certain usage patterns, the existing defenses against this might be insufficient, allowing `pg_multixact/members` files to be removed too early, resulting in data loss. The fix for this includes modifying the server to fail transactions that would result in overwriting old multixact member ID data, and improving autovacuum to ensure it will act proactively to prevent multixact member ID wraparound, as it does for transaction ID wraparound.

- Fix incorrect declaration of `contrib/citext`'s `regexp_matches()` functions (Tom Lane)

These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the `citext` extension, while we have provided corrected declarations in version 1.1 (which is *not* installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO '1.1'` in each database in which `citext` is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that ei-

ther update direction will require dropping and recreating any views or rules that use `citext's regexp_matches()` functions.

- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)

If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- Fix planning of star-schema-style queries (Tom Lane)

Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)

This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)

Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)

This oversight has been seen to lead to “failed to join all relations together” errors in queries involving `LATERAL`, and that might happen in other cases as well.

- Fix possible deadlock at startup when `max_prepared_transactions` is too small (Heikki Linnakangas)
- Don't archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)
- Recursively `fsync()` the data directory after a crash (Abhijit Menon-Sen, Robert Haas)

This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

- Fix autovacuum launcher's possible failure to shut down, if an error occurs after it receives `SIGTERM` (Álvaro Herrera)
- Cope with unexpected signals in `LockBufferForCleanup()` (Andres Freund)

This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.

- Fix crash when doing `COPY IN` to a table with check constraints that contain whole-row references (Tom Lane)

The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)

Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)
- Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)
- Check for interrupts while analyzing index expressions (Jeff Janes)

`ANALYZE` executes index expressions many times; if there are slow functions in such an expression, it's desirable to be able to cancel the `ANALYZE` before that loop finishes.

- Ensure `tableoid` of a foreign table is reported correctly when a `READ COMMITTED` recheck occurs after locking rows in `SELECT FOR UPDATE`, `UPDATE`, or `DELETE` (Etsuro Fujita)
- Add the name of the target server to object description strings for foreign-server user mappings (Álvaro Herrera)
- Include the schema name in object identity strings for conversions (Álvaro Herrera)
- Recommend setting `include_realm` to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)

Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 `pg_hba.conf` entries to IPv4-in-IPv6 addresses (Tom Lane)

This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it's not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let's just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 `pg_hba.conf` entries, which does not seem like a good thing to do in minor releases.)

- Report WAL flush, not insert, position in `IDENTIFY_SYSTEM` replication command (Heikki Linnakangas)

This avoids a possible startup failure in `pg_receivexlog`.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that `pg_ctl` will wait for shutdown (Krystian Bigaj)
- Reduce risk of network deadlock when using libpq's non-blocking mode (Heikki Linnakangas)

When sending large volumes of data, it's important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of `NOTICE` messages during `COPY FROM STDIN`.) This worked properly in the normal blocking mode, but not so much in non-blocking mode. We've modified libpq to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call `PQconsumeInput()` upon read-ready.

- In libpq, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)
- Fix array handling in `ecpg` (Michael Meskes)
- Fix `psql` to sanely handle URIs and conninfo strings as the first parameter to `\connect` (David Fetter, Andrew Dunstan, Álvaro Herrera)

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

- Suppress incorrect complaints from `psql` on some platforms that it failed to write `~/.psql_history` at exit (Tom Lane)

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of libedit. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of libedit. Recommendation: upgrade that library, or use libreadline.

- Fix `pg_dump`'s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)
- In `pg_dump`, fix failure to honor `-Z` compression level option together with `-Fd` (Michael Paquier)
- Make `pg_dump` consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)

This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

- Avoid possible `pg_dump` failure when concurrent sessions are creating and dropping temporary functions (Tom Lane)
- Fix dumping of views that are just `VALUES (...)` but have column aliases (Tom Lane)
- In `pg_upgrade`, force timeline 1 in the new cluster (Bruce Momjian)

This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

- In `pg_upgrade`, check for improperly non-connectable databases before proceeding (Bruce Momjian)
- In `pg_upgrade`, quote directory paths properly in the generated `delete_old_cluster` script (Bruce Momjian)
- In `pg_upgrade`, preserve database-level freezing info properly (Bruce Momjian)

This oversight could cause missing-clog-file errors for tables within the `postgres` and `template1` databases.

- Run `pg_upgrade` and `pg_resetxlog` with restricted privileges on Windows, so that they don't fail when run by an administrator (Muhammad Asif Naeem)
- Improve handling of `readdir()` failures when scanning directories in `initdb` and `pg_basebackup` (Marco Nenciarini)
- Fix slow sorting algorithm in `contrib/intarray` (Tom Lane)
- Fix compile failure on Sparc V8 machines (Rob Rowan)
- Silence some build warnings on macOS (Tom Lane)
- Update time zone data files to `tzdata` release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

## E.75. Release 9.3.6

**Release date:** 2015-02-05

This release contains a variety of fixes from 9.3.5. For information about new features in the 9.3 major release, see Section E.81.

### E.75.1. Migration to Version 9.3.6

A dump/restore is not required for those running 9.3.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)\_Norway” locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian\_Norway”. For details see [http://wiki.postgresql.org/wiki/Changes\\_To\\_Norwegian\\_Locale](http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale)

Also, if you are upgrading from a version earlier than 9.3.5, see Section E.76.

## E.75.2. Changes

- Fix buffer overruns in `to_char()` (Bruce Momjian)

When `to_char()` processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- Fix buffer overrun in replacement `*printf()` functions (Tom Lane)

PostgreSQL includes a replacement implementation of `printf` and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers `e`, `E`, `f`, `F`, `g` or `G`) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use `printf`-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)

Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)

If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message's data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)

Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have `SELECT` privilege on all columns of the table, this could mean exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing's temporary installations on Windows (Noah Misch)

Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named "Norwegian (Bokmål)" (Heikki Linnakangas)

Non-ASCII locale names are problematic since it's not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, "Norwegian\_Norway".

- Avoid possible data corruption if `ALTER DATABASE SET TABLESPACE` is used to move a database to a new tablespace and then shortly later move it back to its original tablespace (Tom Lane)
- Avoid corrupting tables when `ANALYZE` inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)

If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant `pg_class` flags not set though they should be.

- Ensure that unlogged tables are copied correctly during `CREATE DATABASE` or `ALTER DATABASE SET TABLESPACE` (Pavan Deolasee, Andres Freund)
- Fix incorrect processing of `CreateEventTrigStmt.eventname` (Petr Jelinek)

This could result in misbehavior if `CREATE EVENT TRIGGER` were executed as a prepared query, or via extended query protocol.

- Fix `DROP`'s dependency searching to correctly handle the case where a table column is recursively visited before its table (Petr Jelinek, Tom Lane)

This case is only known to arise when an extension creates both a datatype and a table using that datatype. The faulty code might refuse a `DROP EXTENSION` unless `CASCADE` is specified, which should not be required.

- Fix use-of-already-freed-memory problem in `EvalPlanQual` processing (Tom Lane)

In `READ COMMITTED` mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Avoid possible deadlock while trying to acquire tuple locks in `EvalPlanQual` processing (Álvaro Herrera, Mark Kirkwood)
- Fix failure to wait when a transaction tries to acquire a `FOR NO KEY EXCLUSIVE` tuple lock, while multiple other transactions currently hold `FOR SHARE` locks (Álvaro Herrera)
- Fix planning of `SELECT FOR UPDATE` when using a partial index on a child table (Kyotaro Horiguchi)

In `READ COMMITTED` mode, `SELECT FOR UPDATE` must also recheck the partial index's `WHERE` condition when rechecking a recently-updated row to see if it still satisfies the query's `WHERE` condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

- Fix corner case wherein `SELECT FOR UPDATE` could return a row twice, and possibly miss returning other rows (Tom Lane)

In `READ COMMITTED` mode, a `SELECT FOR UPDATE` that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

- Improve performance of `EXPLAIN` with large range tables (Tom Lane)
- Reject duplicate column names in the referenced-columns list of a `FOREIGN KEY` declaration (David Rowley)

This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

- Re-enable error for `SELECT ... OFFSET -1` (Tom Lane)

A negative offset value has been an error since 8.4, but an optimization added in 9.3 accidentally turned the case into a no-op. Restore the expected behavior.

- Restore previous behavior of conversion of domains to JSON (Tom Lane)

This change causes domains over numeric and boolean to be treated like their base types for purposes of conversion to JSON. It worked like that before 9.3.5 and 9.2.9, but was unintentionally changed while fixing a related problem.

- Fix `json_agg()` to not return extra trailing right brackets in its result (Tom Lane)

- Fix bugs in raising a `numeric` value to a large integral power (Tom Lane)

The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

- In `numeric_recv()`, truncate away any fractional digits that would be hidden according to the value's `dscale` field (Tom Lane)

A `numeric` value's display scale (`dscale`) should never be less than the number of nonzero fractional digits; but apparently there's at least one broken client application that transmits binary `numeric` values in which that's true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren't printed. The least risky fix seems to be to truncate away such "hidden" digits on receipt, so that the value is indeed what it prints as.

- Fix incorrect search for shortest-first regular expression matches (Tom Lane)

Matching would often fail when the number of allowed iterations is limited by a `?` quantifier or a bound expression.

- Reject out-of-range numeric timezone specifications (Tom Lane)

Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There's no use-case for such large UTC offsets, so reject them.

- Fix bugs in `tsquery @> tsquery` operator (Heikki Linnakangas)

Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

- Improve `ispell` dictionary's defenses against bad affix files (Tom Lane)
- Allow more than 64K phrases in a thesaurus dictionary (David Boutin)

The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.

- Fix namespace handling in `xpath()` (Ali Akbar)

Previously, the `xml` value resulting from an `xpath()` call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input `xml` value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

- Ensure that whole-row variables expose nonempty column names to functions that pay attention to column names within composite arguments (Tom Lane)

In some contexts, constructs like `row_to_json(tab.*)` may not produce the expected column names. This is fixed properly as of 9.4; in older branches, just ensure that we produce some non-empty name. (In some cases this will be the underlying table's column name rather than the query-assigned alias that should theoretically be visible.)

- Fix mishandling of system columns, particularly `tableoid`, in FDW queries (Etsuro Fujita)
- Fix assorted oversights in range-operator selectivity estimation (Emre Hasegeli)

This patch fixes corner-case "unexpected operator NNNN" planner errors, and improves the selectivity estimates for some other cases.

- Avoid doing `indexed_column = ANY (array)` as an index qualifier if that leads to an inferior plan (Andrew Gierth)

In some cases, `= ANY` conditions applied to non-first index columns would be done as index conditions even though it would be better to use them as simple filter conditions.

- Fix “variable not found in subplan target list” planner failure when an inline-able SQL function taking a composite argument is used in a `LATERAL` subselect and the composite argument is a lateral reference (Tom Lane)
- Fix planner problems with nested append relations, such as inherited tables within `UNION ALL` subqueries (Tom Lane)
- Fail cleanly when a GiST index tuple doesn't fit on a page, rather than going into infinite recursion (Andrew Gierth)
- Exempt tables that have per-table `cost_limit` and/or `cost_delay` settings from autovacuum's global cost balancing rules (Álvaro Herrera)

The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.

- Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)

Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers *only* do anti-wraparound vacuums and not any other work.

- During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)

This prevents scenarios in which unlogged relations might contain garbage data following database crash recovery.

- Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)

This mistake could result in transient errors in queries being executed in hot standby.

- Fix several cases where recovery logic improperly ignored WAL records for `COMMIT/ABORT PREPARED` (Heikki Linnakangas)

The most notable oversight was that `recovery_target_xid` could not be used to stop at a two-phase commit.

- Prevent latest WAL file from being archived a second time at completion of crash recovery (Fujii Masao)
- Avoid creating unnecessary `.ready` marker files for timeline history files (Fujii Masao)
- Fix possible null pointer dereference when an empty prepared statement is used and the `log_statement` setting is `mod` or `ddl` (Fujii Masao)
- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)

This message was originally thought to be essentially a can't-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

- Fix possible corruption of postmaster's list of dynamic background workers (Andres Freund)
- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)
- Warn if macOS's `setlocale()` starts an unwanted extra thread inside the postmaster (Noah Misch)
- Fix processing of repeated `dbname` parameters in `PQconnectdbParams()` (Alex Shulgin)

Unexpected behavior ensued if the first occurrence of `dbname` contained a connection string or URI to be expanded.

- Ensure that `libpq` reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)

Depending on kernel behavior, `libpq` might return an empty error string rather than something useful when the server unexpectedly closed the socket.

- Clear any old error message during `PQreset()` (Heikki Linnakangas)

If `PQreset()` is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the `PGconn`'s error string.

- Properly handle out-of-memory conditions while parsing connection options in `libpq` (Alex Shulgin, Heikki Linnakangas)
- Fix array overrun in `ecpg`'s version of `ParseDateTime()` (Michael Paquier)
- In `initdb`, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)
- Fix `psql`'s `\s` command to work nicely with `libedit`, and add pager support (Stepan Rutz, Tom Lane)

When using `libedit` rather than `readline`, `\s` printed the command history in a fairly unreadable encoded format, and on recent `libedit` versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.

This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with `libedit`. Multiline history entries written by older `psql` versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact `libedit` versions involved.

- Improve consistency of parsing of `psql`'s special variables (Tom Lane)

Allow variant spellings of `on` and `off` (such as `1/0`) for `ECHO_HIDDEN` and `ON_ERROR_ROLLBACK`. Report a warning for unrecognized values for `COMP_KEYWORD_CASE`, `ECHO`, `ECHO_HIDDEN`, `HISTCONTROL`, `ON_ERROR_ROLLBACK`, and `VERBOSITY`. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Make `psql`'s `\watch` command display nulls as specified by `\pset null` (Fujii Masao)
- Fix `psql`'s expanded-mode display to work consistently when using `border = 3` and `linestyle = ascii` or `unicode` (Stephen Frost)
- Fix `pg_dump` to handle comments on event triggers without failing (Tom Lane)
- Allow parallel `pg_dump` to use `--serializable-deferrable` (Kevin Grittner)
- Improve performance of `pg_dump` when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)
- Fix `pg_dumpall` to restore its ability to dump from pre-8.1 servers (Gilles Darold)
- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)
- Fix core dump in `pg_dump --binary-upgrade` on zero-column composite type (Rushabh Lathia)
- Fix failure to `fsync` tables in nondefault tablespaces during `pg_upgrade` (Abhijit Menon-Sen, Andres Freund)

With an operating system crash and some bad luck, this could result in data loss during an upgrade.

- In `pg_upgrade`, cope with cases where the new cluster creates a TOAST table for a table that didn't previously have one (Bruce Momjian)

Previously this could result in failures due to OID conflicts.

- In `pg_upgrade`, don't try to set `autovacuum_multixact_freeze_max_age` for the old cluster (Bruce Momjian)

This could result in failure because not all 9.3.X versions have that parameter. Fortunately, we don't actually need to set it at all.

- In `pg_upgrade`, preserve the transaction ID epoch (Bruce Momjian)

This oversight did not bother PostgreSQL proper, but could confuse some external replication tools.

- Prevent WAL files created by `pg_basebackup -x/-X` from being archived again when the standby is promoted (Andres Freund)
- Fix memory leak in `pg_receivexlog` (Fujii Masao)
- Fix unintended suppression of `pg_receivexlog` verbose messages (Fujii Masao)
- Fix failure of `contrib/auto_explain` to print per-node timing information when doing `EXPLAIN ANALYZE` (Tom Lane)
- Fix upgrade-from-unpackaged script for `contrib/citext` (Tom Lane)
- Avoid integer overflow and buffer overrun in `contrib/hstore`'s `hstore_to_json()` (Heikki Linnakangas)
- Fix recognition of numbers in `hstore_to_json_loose()`, so that JSON numbers and strings are correctly distinguished (Andrew Dunstan)
- Fix block number checking in `contrib/pageinspect`'s `get_raw_page()` (Tom Lane)

The incorrect checking logic could prevent access to some pages in non-main relation forks.

- Fix `contrib/pgcrypto`'s `pgp_sym_decrypt()` to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
- Fix file descriptor leak in `contrib/pg_test_fsync` (Jeff Janes)

This could cause failure to remove temporary files on Windows.

- Handle unexpected query results, especially NULLs, safely in `contrib/tablefunc`'s `connectby()` (Michael Paquier)

`connectby()` previously crashed if it encountered a NULL key value. It now prints that row but doesn't recurse further.

- Avoid a possible crash in `contrib/xml2`'s `xslt_process()` (Mark Simonetti)

`libxslt` seems to have an undocumented dependency on the order in which resources are freed; re-order our calls to avoid a crash.

- Mark some `contrib` I/O functions with correct volatility properties (Tom Lane)

The previous over-conservative marking was immaterial in normal use, but could cause optimization problems or rejection of valid index expression definitions. Since the consequences are not large, we've just adjusted the function definitions in the extension modules' scripts, without changing version numbers.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)

These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

- Fix setup of background workers in `EXEC_BACKEND` builds, eg Windows (Robert Haas)

- Detect incompatible OpenLDAP versions during build (Noah Misch)

With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the `contrib/dblink` regression test.

- In non-MSVC Windows builds, ensure `libpq.dll` is installed with execute permissions (Noah Misch)
- Make `pg_regress` remove any temporary installation it created upon successful exit (Tom Lane)

This results in a very substantial reduction in disk space usage during `make check-world`, since that sequence involves creation of numerous temporary installations.

- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)

Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as `EST`) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

- Update time zone abbreviations lists (Tom Lane)

Add `CST` (China Standard Time) to our lists. Remove references to `ADT` as “Arabia Daylight Time”, an abbreviation that's been out of use since 2007; therefore, claiming there is a conflict with “Atlantic Daylight Time” doesn't seem especially helpful. Fix entirely incorrect GMT offsets for `CKT` (Cook Islands), `FJT`, and `FJST` (Fiji); we didn't even have them on the proper side of the date line.

- Update time zone data files to tzdata release 2015a.

The IANA timezone database has adopted abbreviations of the form `AxST/AxDt` for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than `ACST` for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only `CST`, `EAST`, `EST`, `SAST`, `SAT`, and `WST`, all of which are thought to be mostly historical usage. Note that `SAST` has also been changed to be South Africa Standard Time in the “Default” abbreviation set.

Also, add zone abbreviations `SRET` (Asia/Srednekolymsk) and `XJT` (Asia/Urumqi), and use `WSST/WSDT` for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks & Caicos Islands (America/Grand\_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

## E.76. Release 9.3.5

**Release date:** 2014-07-24

This release contains a variety of fixes from 9.3.4. For information about new features in the 9.3 major release, see Section E.81.

### E.76.1. Migration to Version 9.3.5

A dump/restore is not required for those running 9.3.X.

However, this release corrects a logic error in `pg_upgrade`, as well as an index corruption problem in some GiST indexes. See the first two changelog entries below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.3.4, see Section E.77.

## E.76.2. Changes

- In `pg_upgrade`, remove `pg_multixact` files left behind by `initdb` (Bruce Momjian)

If you used a pre-9.3.5 version of `pg_upgrade` to upgrade a database cluster to 9.3, it might have left behind a file `$PGDATA/pg_multixact/offsets/0000` that should not be there and will eventually cause problems in `VACUUM`. *However, in common cases this file is actually valid and must not be removed.* To determine whether your installation has this problem, run this query as superuser, in any database of the cluster:

```
WITH list(file) AS (SELECT * FROM pg_ls_dir('pg_multixact/offsets'))
SELECT EXISTS (SELECT * FROM list WHERE file = '0000') AND
       NOT EXISTS (SELECT * FROM list WHERE file = '0001') AND
       NOT EXISTS (SELECT * FROM list WHERE file = 'FFFF') AND
       EXISTS (SELECT * FROM list WHERE file != '0000')
AS file_0000_removal_required;
```

If this query returns `t`, manually remove the file `$PGDATA/pg_multixact/offsets/0000`. Do nothing if the query returns `f`.

- Correctly initialize padding bytes in `contrib/btree_gist` indexes on bit columns (Heikki Linnakangas)

This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on bit or bit varying columns should `REINDEX` those indexes after installing this update.

- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)

This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

- Don't clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)

This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.

- Fix corner-case infinite loop during insertion into an SP-GiST text index (Tom Lane)
- Fix incorrect answers from SP-GiST index searches with `-|-` (range adjacency) operator (Heikki Linnakangas)
- Fix wraparound handling for `pg_multixact/members` (Álvaro Herrera)
- Truncate `pg_multixact` during checkpoints, not during `VACUUM` (Álvaro Herrera)

This change ensures that `pg_multixact` segments can't be removed if they'd still be needed during WAL replay after a crash.

- Fix possible inconsistency of all-visible flags after WAL recovery (Heikki Linnakangas)
- Fix possibly-incorrect cache invalidation during nested calls to `ReceiveSharedInvalidMessages` (Andres Freund)
- Fix race condition when updating a tuple concurrently locked by another process (Andres Freund, Álvaro Herrera)
- Fix “could not find pathkey item to sort” planner failures with `UNION ALL` over subqueries reading from tables with inheritance children (Tom Lane)
- Don't assume a subquery's output is unique if there's a set-returning function in its targetlist (David Rowley)

This oversight could lead to misoptimization of constructs like `WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y)`.

- Improve planner to drop constant-NULL inputs of `AND/OR` when possible (Tom Lane)

This change fixes some cases where the more aggressive parameter substitution done by 9.2 and later can lead to a worse plan than older versions produced.

- Ensure that the planner sees equivalent `VARIADIC` and non-`VARIADIC` function calls as equivalent (Tom Lane)

This bug could for example result in failure to use expression indexes involving variadic functions. It might be necessary to re-create such indexes, and/or re-create views including variadic function calls that should match the indexes, for the fix to be effective for existing 9.3 installations.

- Fix handling of nested `JSON` objects in `json_populate_recordset()` and friends (Michael Paquier, Tom Lane)

A nested `JSON` object could result in previous fields of the parent object not being shown in the output.

- Fix identification of input type category in `to_json()` and friends (Tom Lane)

This is known to have led to inadequate quoting of `money` fields in the `JSON` result, and there may have been wrong results for other data types as well.

- Fix failure to detoast fields in composite elements of structured types (Tom Lane)

This corrects cases where `TOAST` pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

- Fix “record type has not been registered” failures with whole-row references to the output of `Append plan nodes` (Tom Lane)
- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)
- Fix query-lifespan memory leak while evaluating the arguments for a function in `FROM` (Tom Lane)
- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O'Dwyer, Greg Stark)
- Fix data encoding error in `hungarian.stop` (Tom Lane)
- Prevent foreign tables from being created with `OIDS` when `default_with_oids` is true (Etsuro Fujita)
- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)

This could cause problems (at least spurious warnings, and at worst an infinite loop) if `CREATE INDEX` or `CLUSTER` were done later in the same transaction.

- Clear `pg_stat_activity.xact_start` during `PREPARE TRANSACTION` (Andres Freund)

After the `PREPARE`, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

- Fix `REASSIGN OWNED` to not fail for text search objects (Álvaro Herrera)
- Prevent `pg_class.relminmxid` values from going backwards during `VACUUM FULL` (Álvaro Herrera)
- Reduce indentation in rule/view dumps to improve readability and avoid excessive whitespace (Greg Stark, Tom Lane)

This change reduces the amount of indentation applied to nested constructs, including some cases that the user probably doesn't think of as nested, such as `UNION` lists. Previously, deeply nested constructs were printed with an amount of whitespace growing as  $O(N^2)$ , which created a performance problem and even risk of out-of-memory failures. Now the indentation is reduced modulo 40, which is initially odd to look at but seems to preserve readability better than simply limiting the indentation would do. Redundant parenthesization of `UNION` lists has been reduced as well.

- Fix dumping of rules/views when subsequent addition of a column has resulted in multiple input columns matching a `USING` specification (Tom Lane)
- Repair view printing for some cases involving functions in `FROM` that return a composite type containing dropped columns (Tom Lane)
- Block signals during postmaster startup (Tom Lane)

This ensures that the postmaster will properly clean up after itself if, for example, it receives `SIGINT` while still starting up.

- Fix client host name lookup when processing `pg_hba.conf` entries that specify host names instead of IP addresses (Tom Lane)

Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.

- Allow the root user to use `postgres -C variable` and `postgres --describe-config` (MauMau)

The prohibition on starting the server as root does not need to extend to these operations, and relaxing it prevents failure of `pg_ctl` in some scenarios.

- Secure Unix-domain sockets of temporary postmasters started during `make check` (Noah Misch)

Any local user able to access the socket file could connect as the server's bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in CVE-2014-0067. This change defends against that risk by placing the server's socket in a temporary, mode 0700 subdirectory of `/tmp`. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.

A useful side effect of this change is to simplify `make check` testing in builds that override `DEFAULT_PGSOCKET_DIR`. Popular non-default values like `/var/run/postgresql` are often not writable by the build user, requiring workarounds that will no longer be necessary.

- Fix tablespace creation WAL replay to work on Windows (MauMau)
- Fix detection of socket creation failures on Windows (Bruce Momjian)
- On Windows, allow new sessions to absorb values of `PGC_BACKEND` parameters (such as `log_connections`) from the configuration file (Amit Kapila)

Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

- Properly quote executable path names on Windows (Nikhil Deshpande)

This oversight could cause `initdb` and `pg_upgrade` to fail on Windows, if the installation path contained both spaces and `@` signs.

- Fix linking of `libpython` on macOS (Tom Lane)

The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

- Avoid buffer bloat in `libpq` when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)

`libpq` could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it's quite far-fetched that data could be continuously transmitted more quickly than the `recv()` loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

- Ensure that LDAP lookup attempts in `libpq` time out as intended (Laurenz Albe)

- Fix `ecpg` to do the right thing when an array of `char *` is the target for a `FETCH` statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)
- Fix `pg_dump` to cope with a materialized view that depends on a table's primary key (Tom Lane)

This occurs if the view's query relies on functional dependency to abbreviate a `GROUP BY` list. `pg_dump` got sufficiently confused that it dumped the materialized view as a regular view.

- Fix parsing of `pg_dumpall`'s `-i` switch (Tom Lane)
- Fix `pg_restore`'s processing of old-style large object comments (Tom Lane)

A direct-to-database restore from an archive file generated by a pre-9.0 version of `pg_dump` would usually fail if the archive contained more than a few comments for large objects.

- Fix `pg_upgrade` for cases where the new server creates a `TOAST` table but the old version did not (Bruce Momjian)

This rare situation would manifest as “relation OID mismatch” errors.

- In `pg_upgrade`, preserve `pg_database.datminmxid` and `pg_class.relminmxid` values from the old cluster, or insert reasonable values when upgrading from pre-9.3; also defend against unreasonable values in the core server (Bruce Momjian, Álvaro Herrera, Tom Lane)

These changes prevent scenarios in which autovacuum might insist on scanning the entire cluster's contents immediately upon starting the new cluster, or in which tracking of unfrozen MXID values might be disabled completely.

- Prevent `contrib/auto_explain` from changing the output of a user's `EXPLAIN` (Tom Lane)

If `auto_explain` is active, it could cause an `EXPLAIN (ANALYZE, TIMING OFF)` command to nonetheless print timing information.

- Fix query-lifespan memory leak in `contrib/dblink` (MauMau, Joe Conway)
- In `contrib/pgcrypto` functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)
- Prevent use of already-freed memory in `contrib/pgstattuple`'s `pgstat_heap()` (Noah Misch)
- In `contrib/uuid-osp`, cache the state of the OSSP UUID library across calls (Tom Lane)

This improves the efficiency of UUID generation and reduces the amount of entropy drawn from `/dev/urandom`, on platforms that have that.

- Update time zone data files to `tzdata` release 2014e for DST law changes in Crimea, Egypt, and Morocco.

## E.77. Release 9.3.4

**Release date:** 2014-03-20

This release contains a variety of fixes from 9.3.3. For information about new features in the 9.3 major release, see Section E.81.

### E.77.1. Migration to Version 9.3.4

A dump/restore is not required for those running 9.3.X.

However, the error fixed in the first changelog entry below could have resulted in corrupt data on standby servers. It may be prudent to reinitialize standby servers from fresh base backups after installing this update.

Also, if you are upgrading from a version earlier than 9.3.3, see Section E.78.

## E.77.2. Changes

- Fix WAL replay of locking an already-updated tuple (Andres Freund, Álvaro Herrera)

This error caused updated rows to not be found by index scans, resulting in inconsistent query results depending on whether an index scan was used. Subsequent processing could result in constraint violations, since the previously updated row would not be found by later index searches, thus possibly allowing conflicting rows to be inserted. Since this error is in WAL replay, it would only manifest during crash recovery or on standby servers. The improperly-replayed case most commonly arises when a table row that is referenced by a foreign-key constraint is updated concurrently with creation of a referencing row.

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)

Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.

- Avoid race condition in checking transaction commit status during receipt of a NOTIFY message (Marko Tiikkaja)

This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.

- Allow materialized views to be referenced in UPDATE and DELETE commands (Michael Paquier)

Previously such queries failed with a complaint about not being able to lock rows in the materialized view.

- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)

This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- Remove incorrect code that tried to allow OVERLAPS with single-element row arguments (Joshua Yanovski)

This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- Avoid getting more than AccessShareLock when de-parsing a rule or view (Dean Rasheed)

This oversight resulted in `pg_dump` unexpectedly acquiring `RowExclusiveLock` locks on tables mentioned as the targets of `INSERT/UPDATE/DELETE` commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, `ShareLock` on those tables.

- Improve performance of index endpoint probes during planning (Tom Lane)

This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

- Use non-default selectivity estimates for `value IN (list)` and `value operator ANY (array)` expressions when the righthand side is a stable expression (Tom Lane)
- Remove the correct per-database statistics file during `DROP DATABASE` (Tomas Vondra)

This fix prevents a permanent leak of statistics file space. Users who have done many `DROP DATABASE` commands since upgrading to PostgreSQL 9.3 may wish to check their statistics directory and delete statistics files that do not correspond to any existing database. Please note that `db_0.stat` should not be removed.

- Fix walsender ping logic to avoid inappropriate disconnects under continuous load (Andres Freund, Heikki Linnakangas)

walsender failed to send ping messages to the client if it was constantly busy sending WAL data; but it expected to see ping responses despite that, and would therefore disconnect once `wal_sender_timeout` elapsed.

- Fix walsender's failure to shut down cleanly when client is `pg_receivexlog` (Fujii Masao)
- Check WAL level and hot standby parameters correctly when doing crash recovery that will be followed by archive recovery (Heikki Linnakangas)
- Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)
- Add read-only `data_checksums` parameter to display whether page checksums are enabled (Heikki Linnakangas)

Without this parameter, determining the state of checksum processing was difficult.

- Prevent interrupts while reporting non-`ERROR` messages (Tom Lane)

This guards against rare server-process freezeups due to recursive entry to `syslog()`, and perhaps other related problems.

- Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)
- Fix tracking of `psql` script line numbers during `\copy` from out-of-line data (Kumar Rajeev Rastogi, Amit Khandekar)

`\copy ... from` incremented the script file line number for each data line, even if the data was not coming from the script file. This mistake resulted in wrong line numbers being reported for any errors occurring later in the same script file.

- Fix `contrib/postgres_fdw` to handle multiple join conditions properly (Tom Lane)

This oversight could result in sending `WHERE` clauses to the remote server for execution even though the clauses are not known to have the same semantics on the remote server (for example, clauses that use non-built-in operators). The query might succeed anyway, but it could also fail with errors from the remote server, or worse give silently wrong answers.

- Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)
- Update time zone data files to `tzdata` release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

## E.78. Release 9.3.3

**Release date:** 2014-02-20

This release contains a variety of fixes from 9.3.2. For information about new features in the 9.3 major release, see Section E.81.

### E.78.1. Migration to Version 9.3.3

A dump/restore is not required for those running 9.3.X.

However, several of the issues corrected in this release could have resulted in corruption of foreign-key constraints; that is, there might now be referencing rows for which there is no matching row in the referenced table. It may be worthwhile to recheck such constraints after installing this update. The simplest way to do that is to drop and recreate each suspect constraint; however, that will require taking an exclusive lock on both tables, so it is unlikely to be acceptable in production databases. Alternatively, you can do a manual join query between the two tables to look for unmatched rows.

Note also the requirement for replication standby servers to be upgraded before their master server is upgraded.

Also, if you are upgrading from a version earlier than 9.3.2, see Section E.79.

## E.78.2. Changes

- Shore up `GRANT ... WITH ADMIN OPTION` restrictions (Noah Misch)

Granting a role without `ADMIN OPTION` is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing `SET ROLE` first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or `SECURITY DEFINER` functions. (CVE-2014-0060)

- Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)

The primary role of PL validator functions is to be called implicitly during `CREATE FUNCTION`, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

- Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)

If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of `CREATE INDEX`, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

- Prevent buffer overrun with long datetime strings (Noah Misch)

The `MAXDATELEN` constant was too small for the longest possible value of type `interval`, allowing a buffer overrun in `interval_out()`. Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The `ecpg` library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

- Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)

Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

- Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)

Use `strncpy()` and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

- Avoid crashing if `crypt()` returns NULL (Honza Horak, Bruce Momjian)

There are relatively few scenarios in which `crypt()` could return NULL, but `contrib/chkpass` would crash if it did. One practical case in which this could be an issue is if `libc` is configured to refuse to execute unapproved hashing algorithms (e.g., "FIPS mode"). (CVE-2014-0066)

- Document risks of `make check` in the regression testing instructions (Noah Misch, Tom Lane)

Since the temporary server started by `make check` uses "trust" authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate

changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using `make check` when there are untrusted users on the same machine. (CVE-2014-0067)

- Rework tuple freezing protocol (Álvaro Herrera, Andres Freund)

The logic for tuple freezing was unable to handle some cases involving freezing of *multixact* IDs, with the practical effect that shared row-level locks might be forgotten once old enough.

Fixing this required changing the WAL record format for tuple freezing. While this is no issue for standalone servers, when using replication it means that *standby servers must be upgraded to 9.3.3 or later before their masters are*. An older standby will be unable to interpret freeze records generated by a newer master, and will fail with a PANIC message. (In such a case, upgrading the standby should be sufficient to let it resume execution.)

- Create separate GUC parameters to control multixact freezing (Álvaro Herrera)

9.3 requires multixact tuple labels to be frozen before they grow too old, in the same fashion as plain transaction ID labels have been frozen for some time. Previously, the transaction ID freezing parameters were used for multixact IDs too; but since the consumption rates of transaction IDs and multixact IDs can be quite different, this did not work very well. Introduce new settings `vacuum_multixact_freeze_min_age`, `vacuum_multixact_freeze_table_age`, and `autovacuum_multixact_freeze_max_age` to control when to freeze multixacts.

- Account for remote row locks propagated by local updates (Álvaro Herrera)

If a row was locked by transaction A, and transaction B updated it, the new version of the row created by B would be locked by A, yet visible only to B. If transaction B then again updated the row, A's lock wouldn't get checked, thus possibly allowing B to complete when it shouldn't. This case is new in 9.3 since prior versions did not have any types of row locking that would permit another transaction to update the row at all.

This oversight could allow referential integrity checks to give false positives (for instance, allow deletes that should have been rejected). Applications using the new commands `SELECT FOR KEY SHARE` and `SELECT FOR NO KEY UPDATE` might also have suffered locking failures of this kind.

- Prevent “forgetting” valid row locks when one of several holders of a row lock aborts (Álvaro Herrera)

This was yet another mechanism by which a shared row lock could be lost, thus possibly allowing updates that should have been prevented by foreign-key constraints.

- Fix incorrect logic during update chain locking (Álvaro Herrera)

This mistake could result in spurious “could not serialize access due to concurrent update” errors in `REPEATABLE READ` and `SERIALIZABLE` transaction isolation modes.

- Handle wraparound correctly during extension or truncation of `pg_multixact/members` (Andres Freund, Álvaro Herrera)
- Fix handling of 5-digit filenames in `pg_multixact/members` (Álvaro Herrera)

As of 9.3, these names can be more than 4 digits, but the directory cleanup code ignored such files.

- Improve performance of multixact cache code (Álvaro Herrera)
- Optimize updating a row that's already locked by the same transaction (Andres Freund, Álvaro Herrera)

This fixes a performance regression from pre-9.3 versions when doing `SELECT FOR UPDATE` followed by `UPDATE/DELETE`.

- During archive recovery, prefer highest timeline number when WAL segments with the same ID are present in both the archive and `pg_xlog/` (Kyotaro Horiguchi)

Previously, not-yet-archived segments could get ignored during recovery. This reverts an undesirable behavioral change in 9.3.0 back to the way things worked pre-9.3.

- Fix possible mis-replay of WAL records when some segments of a relation aren't full size (Greg Stark, Tom Lane)

The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)

In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix WAL logging of visibility map changes (Heikki Linnakangas)
- Fix improper locking of btree index pages while replaying a `VACUUM` operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)

This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

The previous coding risked index corruption in the event of a partial-page write during a system crash.

- When `pause_at_recovery_target` and `recovery_target_inclusive` are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)
- Ensure walreceiver sends hot-standby feedback messages on time even when there is a continuous stream of data (Andres Freund, Amit Kapila)
- Prevent timeout interrupts from taking control away from mainline code unless `ImmediateInterruptOK` is set (Andres Freund, Tom Lane)

This is a serious issue for any application making use of statement timeouts, as it could cause all manner of strange failures after a timeout occurred. We have seen reports of “stuck” spinlocks, ERRORS being unexpectedly promoted to PANICs, unkillable backends, and other misbehaviors.

- Fix race conditions during server process exit (Robert Haas)

Ensure that signal handlers don't attempt to use the process's `MyProc` pointer after it's no longer valid.

- Fix race conditions in walsender shutdown logic and walreceiver `SIGHUP` signal handler (Tom Lane)
- Fix unsafe references to `errno` within error reporting logic (Christian Kruse)

This would typically lead to odd behaviors such as missing or inappropriate `HINT` fields.

- Fix possible crashes from using `ereport()` too early during server startup (Tom Lane)

The principal case we've seen in the field is a crash if the server is started in a directory it doesn't have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)

This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (`U&" . . . "` syntax) containing escapes (Tom Lane)

A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn't need truncation after de-escaping.

- Fix parsing of Unicode literals and identifiers just before the end of a command string or function body (Tom Lane)
- Allow keywords that are type names to be used in lists of roles (Stephen Frost)

A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as `DROP ROLE`.

- Fix parser crash for `EXISTS(SELECT * FROM zero_column_table)` (Tom Lane)
- Fix possible crash due to invalid plan for nested sub-selects, such as `WHERE (... x IN (SELECT ...) ...) IN (SELECT ...)` (Tom Lane)
- Fix mishandling of `WHERE` conditions pulled up from a `LATERAL` subquery (Tom Lane)

The typical symptom of this bug was a "JOIN qualification cannot refer to other relations" error, though subtle logic errors in created plans seem possible as well.

- Disallow `LATERAL` references to the target table of an `UPDATE/DELETE` (Tom Lane)

While this might be allowed in some future release, it was unintentional in 9.3, and didn't work quite right anyway.

- Fix `UPDATE/DELETE` of an inherited target table that has `UNION ALL` subqueries (Tom Lane)

Without this fix, `UNION ALL` subqueries aren't correctly inserted into the update plans for inheritance child tables after the first one, typically resulting in no update happening for those child table(s).

- Fix `ANALYZE` to not fail on a column that's a domain over a range type (Tom Lane)
- Ensure that `ANALYZE` creates statistics for a table column even when all the values in it are "too wide" (Tom Lane)

`ANALYZE` intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

- In `ALTER TABLE ... SET TABLESPACE`, allow the database's default tablespace to be used without a permissions check (Stephen Frost)

`CREATE TABLE` has always allowed such usage, but `ALTER TABLE` didn't get the memo.

- Fix support for extensions containing event triggers (Tom Lane)
- Fix "cannot accept a set" error when some arms of a `CASE` return a set and others don't (Tom Lane)
- Fix memory leakage in JSON functions (Craig Ringer)
- Properly distinguish numbers from non-numbers when generating JSON output (Andrew Dunstan)
- Fix checks for all-zero client addresses in `pgstat` functions (Kevin Grittner)
- Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)

Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

- Fix possible misbehavior in `plainto_tsquery()` (Heikki Linnakangas)

Use `memmove()` not `memcpy()` for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it's certainly risky.

- Fix placement of permissions checks in `pg_start_backup()` and `pg_stop_backup()` (Andres Freund, Magnus Hagander)

The previous coding might attempt to do catalog access when it shouldn't.

- Accept `SHIFT_JIS` as an encoding name for locale checking purposes (Tatsuo Ishii)
- Fix \*-qualification of named parameters in SQL-language functions (Tom Lane)

Given a composite-type parameter named `foo`, `$1.*` worked fine, but `foo.*` not so much.

- Fix misbehavior of `PQhost()` on Windows (Fujii Masao)

It should return `localhost` if no host has been specified.

- Improve error handling in `libpq` and `psql` for failures during `COPY TO STDOUT/FROM STDIN` (Tom Lane)

In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during `COPY FROM STDIN`. Variants of that scenario might be possible in older versions, or with other client applications.

- Fix incorrect translation handling in some `psql \d` commands (Peter Eisentraut, Tom Lane)
- Ensure `pg_basebackup`'s background process is killed when exiting its foreground process (Magnus Hagander)
- Fix possible incorrect printing of filenames in `pg_basebackup`'s verbose mode (Magnus Hagander)
- Avoid including tablespaces inside PGDATA twice in base backups (Dimitri Fontaine, Magnus Hagander)
- Fix misaligned descriptors in `ecpg` (MauMau)
- In `ecpg`, handle lack of a hostname in the connection parameters properly (Michael Meskes)
- Fix performance regression in `contrib/dblink` connection startup (Joe Conway)

Avoid an unnecessary round trip when client and server encodings match.

- In `contrib/isn`, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
- Fix `contrib/pgbench`'s progress logging to avoid overflow when the scale factor is large (Tatsuo Ishii)
- Fix `contrib/pg_stat_statement`'s handling of `CURRENT_DATE` and related constructs (Kyotaro Horiguchi)
- Improve lost-connection error handling in `contrib/postgres_fdw` (Tom Lane)
- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)
- In Mingw and Cygwin builds, install the `libpq` DLL in the `bin` directory (Andrew Dunstan)

This duplicates what the MSVC build has long done. It should fix problems with programs like `psql` failing to start because they can't find the DLL.

- Avoid using the deprecated `dllwrap` tool in Cygwin builds (Marco Atzeri)
- Enable building with Visual Studio 2013 (Brar Piening)
- Don't generate plain-text `HISTORY` and `src/test/regress/README` files anymore (Tom Lane)

These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they'll just be stubs directing the reader to consult the main documentation. The plain-text `INSTALL` file will still be maintained, as there is arguably a use-case for that.

- Update time zone data files to tzdata release 2013i for DST law changes in Jordan and historical changes in Cuba.

In addition, the zones `Asia/Riyadh87`, `Asia/Riyadh88`, and `Asia/Riyadh89` have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

## E.79. Release 9.3.2

**Release date:** 2013-12-05

This release contains a variety of fixes from 9.3.1. For information about new features in the 9.3 major release, see Section E.81.

### E.79.1. Migration to Version 9.3.2

A dump/restore is not required for those running 9.3.X.

However, this release corrects a number of potential data corruption issues. See the first three changelog entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.3.1, see Section E.80.

### E.79.2. Changes

- Fix `VACUUM`'s tests to see whether it can update `relfrozenxid` (Andres Freund)

In some cases `VACUUM` (either manual or autovacuum) could incorrectly advance a table's `relfrozenxid` value, allowing tuples to escape freezing, causing those rows to become invisible once  $2^{31}$  transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it's not zero. In 9.2.0 and later, the probability of loss is higher, and it's also possible to get “could not access status of transaction” errors as a consequence of this bug. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.

The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having `vacuum_freeze_table_age` set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than  $2^{31}$  update transactions in its lifetime (check this with `SELECT txid_current() < 2^31`).

- Fix multiple bugs in MultiXactId freezing (Andres Freund, Álvaro Herrera)

These bugs could lead to “could not access status of transaction” errors, or to duplicate or vanishing rows. Users upgrading from releases prior to 9.3.0 are not affected.

The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having `vacuum_freeze_table_age` set to zero. This will fix latent corruption but will not be able to fix all pre-existing data errors.

As a separate issue, these bugs can also cause standby servers to get out of sync with the primary, thus exhibiting data errors that are not in the primary. Therefore, it's recommended that 9.3.0 and 9.3.1 standby servers be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- Fix initialization of `pg_clog` and `pg_subtrans` during hot standby startup (Andres Freund, Heikki Linnakangas)

This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been

deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It's recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- Fix multiple bugs in update chain traversal (Andres Freund, Álvaro Herrera)

These bugs could result in incorrect behavior, such as locking or even updating the wrong row, in the presence of concurrent updates. Spurious “unable to fetch updated version of tuple” errors were also possible.

- Fix dangling-pointer problem in fast-path locking (Tom Lane)

This could lead to corruption of the lock data structures in shared memory, causing “lock already held” and other odd errors.

- Fix assorted race conditions in timeout management (Tom Lane)

These errors could result in a server process becoming unresponsive because it had blocked SI-GALRM and/or SIGINT.

- Truncate `pg_multixact` contents during WAL replay (Andres Freund)

This avoids ever-increasing disk space consumption in standby servers.

- Ensure an anti-wraparound `VACUUM` counts a page as scanned when it's only verified that no tuples need freezing (Sergey Burladyan, Jeff Janes)

This bug could result in failing to advance `relfrozenxid`, so that the table would still be thought to need another anti-wraparound vacuum. In the worst case the database might even shut down to prevent wraparound.

- Fix full-table-vacuum request mechanism for MultiXactIds (Andres Freund)

This bug could result in large amounts of useless autovacuum activity.

- Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)

This could lead to transient wrong answers or query failures.

- Fix “unexpected `spgdoinsert()` failure” error during SP-GiST index creation (Teodor Sigaev)
- Fix assorted bugs in materialized views (Kevin Grittner, Andres Freund)
- Re-allow duplicate table aliases if they're within aliased JOINS (Tom Lane)

Historically PostgreSQL has accepted queries like

```
SELECT ... FROM tab1 x CROSS JOIN (tab2 x CROSS JOIN tab3 y) z
```

although a strict reading of the SQL standard would forbid the duplicate usage of table alias `x`. A misguided change in 9.3.0 caused it to reject some such cases that were formerly accepted. Restore the previous behavior.

- Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a `sub-SELECT` (Tom Lane)

This avoids unexpected results due to extra evaluations of the volatile function.

- Fix planner's processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)

This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN` syntax.

- Fix incorrect planning in cases where the same non-strict expression appears in multiple `WHERE` and outer `JOIN` equality clauses (Tom Lane)
- Fix planner crash with whole-row reference to a subquery (Tom Lane)
- Fix incorrect generation of optimized `MIN()/MAX()` plans for inheritance trees (Tom Lane)

The planner could fail in cases where the `MIN()/MAX()` argument was an expression rather than a simple variable.

- Fix premature deletion of temporary files (Andres Freund)
- Prevent intra-transaction memory leak when printing range values (Tom Lane)

This fix actually cures transient memory leaks in any datatype output function, but range types are the only ones known to have had a significant problem.

- Fix memory leaks when reloading configuration files (Heikki Linnakangas, Hari Babu)
- Prevent incorrect display of dropped columns in `NOT NULL` and `CHECK` constraint violation messages (Michael Paquier and Tom Lane)
- Allow default arguments and named-argument notation for window functions (Tom Lane)

Previously, these cases were likely to crash.

- Suppress trailing whitespace on each line when pretty-printing rules and views (Tom Lane)

9.3.0 generated such whitespace in many more cases than previous versions did. To reduce unexpected behavioral changes, suppress unnecessary whitespace in all cases.

- Fix possible read past end of memory in rule printing (Peter Eisentraut)
- Fix array slicing of `int2vector` and `oidvector` values (Tom Lane)

Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.

- Return a valid JSON value when converting an empty `hstore` value to `json` (Oskari Saarenmaa)
- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)

In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the `timeofday` function to honor the simple GMT offset zone.

- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)
- Properly quote generated command lines in `pg_ctl` (Naoya Anzai and Tom Lane)

This fix applies only to Windows.

- Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via `ALTER DATABASE SET` (Kevin Grittner)

Previously, the generated script would fail during restore.

- Fix `pg_isready` to handle its `-d` option properly (Fabrízio de Royes Mello and Fujii Masao)
- Fix parsing of WAL file names in `pg_receivexlog` (Heikki Linnakangas)

This error made `pg_receivexlog` unable to restart streaming after stopping, once at least 4 GB of WAL had been written.

- Report out-of-disk-space failures properly in `pg_upgrade` (Peter Eisentraut)
- Make `ecpg` search for quoted cursor names case-sensitively (Zoltán Böszörményi)
- Fix `ecpg`'s processing of lists of variables declared `varchar` (Zoltán Böszörményi)
- Make `contrib/lo` defend against incorrect trigger definitions (Marc Cousin)

- Update time zone data files to tzdata release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations WIB, WIT, WITA for Indonesia.

## E.80. Release 9.3.1

**Release date:** 2013-10-10

This release contains a variety of fixes from 9.3.0. For information about new features in the 9.3 major release, see Section E.81.

### E.80.1. Migration to Version 9.3.1

A dump/restore is not required for those running 9.3.X.

However, if you use the `hstore` extension, see the first changelog entry.

### E.80.2. Changes

- Ensure new-in-9.3 JSON functionality is added to the `hstore` extension during an update (Andrew Dunstan)

Users who upgraded a pre-9.3 database containing `hstore` should execute

```
ALTER EXTENSION hstore UPDATE;
```

after installing 9.3.1, to add two new JSON functions and a cast. (If `hstore` is already up to date, this command does nothing.)

- Fix memory leak when creating B-tree indexes on range columns (Heikki Linnakangas)
- Fix memory leak caused by `lo_open()` failure (Heikki Linnakangas)
- Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)
- Fix deadlock bug in `libpq` when using SSL (Stephen Frost)
- Fix timeline handling bugs in `pg_receivexlog` (Heikki Linnakangas, Andrew Gieth)
- Prevent `CREATE FUNCTION` from checking `SET` variables unless function body checking is enabled (Tom Lane)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)

## E.81. Release 9.3

**Release date:** 2013-09-09

### E.81.1. Overview

Major enhancements in PostgreSQL 9.3 include:

- Add materialized views
- Make simple views auto-updatable
- Add many features for the `JSON` data type, including operators and functions to extract elements from `JSON` values
- Implement SQL-standard `LATERAL` option for `FROM`-clause subqueries and function calls
- Allow foreign data wrappers to support writes (inserts/updates/deletes) on foreign tables
- Add a Postgres foreign data wrapper to allow access to other Postgres servers
- Add support for event triggers
- Add optional ability to checksum data pages and report corruption

- Prevent non-key-field row updates from blocking foreign key checks
- Greatly reduce System V shared memory requirements

The above items are explained in more detail in the sections below.

## E.81.2. Migration to Version 9.3

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.3 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

### E.81.2.1. Server Settings

- Rename `replication_timeout` to `wal_sender_timeout` (Amit Kapila)

This setting controls the WAL sender timeout.

- Require superuser privileges to set `commit_delay` because it can now potentially delay other sessions (Simon Riggs)
- Allow in-memory sorts to use their full memory allocation (Jeff Janes)

Users who have set `work_mem` based on the previous behavior may need to revisit that setting.

### E.81.2.2. Other

- Throw an error if a tuple to be updated or deleted has already been updated or deleted by a `BEFORE` trigger (Kevin Grittner)

Formerly, the originally-intended update was silently skipped, resulting in logical inconsistency since the trigger might have propagated data to other places based on the intended update. Now an error is thrown to prevent the inconsistent results from being committed. If this change affects your application, the best solution is usually to move the data-propagation actions to an `AFTER` trigger.

This error will also be thrown if a query invokes a volatile function that modifies rows that are later modified by the query itself. Such cases likewise previously resulted in silently skipping updates.

- Change multicolumn `ON UPDATE SET NULL/SET DEFAULT` foreign key actions to affect all columns of the constraint, not just those changed in the `UPDATE` (Tom Lane)

Previously, we would set only those referencing columns that correspond to referenced columns that were changed by the `UPDATE`. This was what was required by SQL-92, but more recent editions of the SQL standard specify the new behavior.

- Force cached plans to be replanned if the `search_path` changes (Tom Lane)

Previously, cached plans already generated in the current session were not redone if the query was re-executed with a new `search_path` setting, resulting in surprising behavior.

- Fix `to_number()` to properly handle a period used as a thousands separator (Tom Lane)

Previously, a period was considered to be a decimal point even when the locale says it isn't and the `D` format code is used to specify use of the locale-specific decimal point. This resulted in wrong answers if `FM` format was also used.

- Fix `STRICT` non-set-returning functions that have set-returning functions in their arguments to properly return null rows (Tom Lane)

A null value passed to the strict function should result in a null output, but instead, that output row was suppressed entirely.

- Store WAL in a continuous stream, rather than skipping the last 16MB segment every 4GB (Heikki Linnakangas)

Previously, WAL files with names ending in `FF` were not used because of this skipping. If you have WAL backup or restore scripts that took this behavior into account, they will need to be adjusted.

- In `pg_constraint.confmatchtype`, store the default foreign key match type (`non-FULL`, `non-PARTIAL`) as `s` for “simple” (Tom Lane)

Previously this case was represented by `u` for “unspecified”.

### E.81.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.3 and the previous major release.

#### E.81.3.1. Server

##### E.81.3.1.1. Locking

- Prevent non-key-field row updates from blocking foreign key checks (Álvaro Herrera, Noah Misch, Andres Freund, Alexander Shulgin, Marti Raudsepp, Alexander Shulgin)

This change improves concurrency and reduces the probability of deadlocks when updating tables involved in a foreign-key constraint. `UPDATES` that do not change any columns referenced in a foreign key now take the new `NO KEY UPDATE` lock mode on the row, while foreign key checks use the new `KEY SHARE` lock mode, which does not conflict with `NO KEY UPDATE`. So there is no blocking unless a foreign-key column is changed.

- Add configuration variable `lock_timeout` to allow limiting how long a session will wait to acquire any one lock (Zoltán Böszörményi)

##### E.81.3.1.2. Indexes

- Add SP-GiST support for range data types (Alexander Korotkov)
- Allow GiST indexes to be unlogged (Jeevan Chalke)
- Improve performance of GiST index insertion by randomizing the choice of which page to descend to when there are multiple equally good alternatives (Heikki Linnakangas)
- Improve concurrency of hash index operations (Robert Haas)

##### E.81.3.1.3. Optimizer

- Collect and use histograms of upper and lower bounds, as well as range lengths, for range types (Alexander Korotkov)
- Improve optimizer's cost estimation for index access (Tom Lane)
- Improve optimizer's hash table size estimate for doing `DISTINCT` via hash aggregation (Tom Lane)
- Suppress no-op Result and Limit plan nodes (Kyotaro Horiguchi, Amit Kapila, Tom Lane)
- Reduce optimizer overhead by not keeping plans on the basis of cheap startup cost when the optimizer only cares about total cost overall (Tom Lane)

##### E.81.3.1.4. General Performance

- Add `COPY FREEZE` option to avoid the overhead of marking tuples as frozen later (Simon Riggs, Jeff Davis)
- Improve performance of `NUMERIC` calculations (Kyotaro Horiguchi)
- Improve synchronization of sessions waiting for `commit_delay` (Peter Geoghegan)

This greatly improves the usefulness of `commit_delay`.

- Improve performance of the `CREATE TEMPORARY TABLE ... ON COMMIT DELETE ROWS` option by not truncating such temporary tables in transactions that haven't touched any temporary tables (Heikki Linnakangas)

- Make vacuum recheck visibility after it has removed expired tuples (Pavan Deolasee)

This increases the chance of a page being marked as all-visible.

- Add per-resource-owner lock caches (Jeff Janes)

This speeds up lock bookkeeping at statement completion in multi-statement transactions that hold many locks; it is particularly useful for `pg_dump`.

- Avoid scanning the entire relation cache at commit of a transaction that creates a new relation (Jeff Janes)

This speeds up sessions that create many tables in successive small transactions, such as a `pg_restore` run.

- Improve performance of transactions that drop many relations (Tomas Vondra)

#### **E.81.3.1.5. Monitoring**

- Add optional ability to checksum data pages and report corruption (Simon Riggs, Jeff Davis, Greg Smith, Ants Aasma)

The checksum option can be set during `initdb`.

- Split the statistics collector's data file into separate global and per-database files (Tomas Vondra)

This reduces the I/O required for statistics tracking.

- Fix the statistics collector to operate properly in cases where the system clock goes backwards (Tom Lane)

Previously, statistics collection would stop until the time again reached the latest time previously recorded.

- Emit an informative message to postmaster standard error when we are about to stop logging there (Tom Lane)

This should help reduce user confusion about where to look for log output in common configurations that log to standard error only during postmaster startup.

#### **E.81.3.1.6. Authentication**

- When an authentication failure occurs, log the relevant `pg_hba.conf` line, to ease debugging of unintended failures (Magnus Hagander)

- Improve LDAP error reporting and documentation (Peter Eisentraut)

- Add support for specifying LDAP authentication parameters in URL format, per RFC 4516 (Peter Eisentraut)

- Change the `ssl_ciphers` parameter to start with `DEFAULT`, rather than `ALL`, then remove insecure ciphers (Magnus Hagander)

This should yield a more appropriate SSL cipher set.

- Parse and load `pg_ident.conf` once, not during each connection (Amit Kapila)

This is similar to how `pg_hba.conf` is processed.

#### **E.81.3.1.7. Server Settings**

- Greatly reduce System V shared memory requirements (Robert Haas)

On Unix-like systems, `mmap()` is now used for most of PostgreSQL's shared memory. For most users, this will eliminate any need to adjust kernel parameters for shared memory.

- Allow the postmaster to listen on multiple Unix-domain sockets (Honza Horák)

The configuration parameter `unix_socket_directory` is replaced by `unix_socket_directories`, which accepts a list of directories.

- Allow a directory of configuration files to be processed (Magnus Hagander, Greg Smith, Selena Deckelmann)

Such a directory is specified with `include_dir` in the server configuration file.

- Increase the maximum `initdb`-configured value for `shared_buffers` to 128MB (Robert Haas)

This is the maximum value that `initdb` will attempt to set in `postgresql.conf`; the previous maximum was 32MB.

- Remove the external PID file, if any, on postmaster exit (Peter Eisentraut)

### E.81.3.2. Replication and Recovery

- Allow a streaming replication standby to follow a timeline switch (Heikki Linnakangas)

This allows streaming standby servers to receive WAL data from a slave newly promoted to master status. Previously, other standbys would require a resync to begin following the new master.

- Add SQL functions `pg_is_in_backup()` and `pg_backup_start_time()` (Gilles Darold)

These functions report the status of base backups.

- Improve performance of streaming log shipping with `synchronous_commit` disabled (Andres Freund)
- Allow much faster promotion of a streaming standby to primary (Simon Riggs, Kyotaro Horiguchi)
- Add the last checkpoint's redo location to `pg_controldata`'s output (Fujii Masao)

This information is useful for determining which WAL files are needed for restore.

- Allow tools like `pg_receivexlog` to run on computers with different architectures (Heikki Linnakangas)

WAL files can still only be replayed on servers with the same architecture as the primary; but they can now be transmitted to and stored on machines of any architecture, since the streaming replication protocol is now machine-independent.

- Make `pg_basebackup --write-recovery-conf` output a minimal `recovery.conf` file (Zoltán Böszörményi, Magnus Hagander)

This simplifies setting up a standby server.

- Allow `pg_receivexlog` and `pg_basebackup --xlog-method` to handle streaming timeline switches (Heikki Linnakangas)
- Add `wal_receiver_timeout` parameter to control the WAL receiver's timeout (Amit Kapila)

This allows more rapid detection of connection failure.

- Change the WAL record format to allow splitting the record header across pages (Heikki Linnakangas)

The new format is slightly more compact, and is more efficient to write.

### E.81.3.3. Queries

- Implement SQL-standard `LATERAL` option for `FROM`-clause subqueries and function calls (Tom Lane)

This feature allows subqueries and functions in `FROM` to reference columns from other tables in the `FROM` clause. The `LATERAL` keyword is optional for functions.

- Add support for piping `COPY` and `psql \copy` data to/from an external program (Etsuro Fujita)
- Allow a multirow `VALUES` clause in a rule to reference `OLD/NEW` (Tom Lane)

#### **E.81.3.4. Object Manipulation**

- Add support for event triggers (Dimitri Fontaine, Robert Haas, Álvaro Herrera)

This allows server-side functions written in event-enabled languages to be called when DDL commands are run.

- Allow foreign data wrappers to support writes (inserts/updates/deletes) on foreign tables (KaiGai Kohei)
- Add `CREATE SCHEMA ... IF NOT EXISTS` clause (Fabrício de Royes Mello)
- Make `REASSIGN OWNED` also change ownership of shared objects (Álvaro Herrera)
- Make `CREATE AGGREGATE` complain if the given initial value string is not valid input for the transition datatype (Tom Lane)
- Suppress `CREATE TABLE`'s messages about implicit index and sequence creation (Robert Haas)

These messages now appear at `DEBUG1` verbosity, so that they will not be shown by default.

- Allow `DROP TABLE IF EXISTS` to succeed when a non-existent schema is specified in the table name (Bruce Momjian)

Previously, it threw an error if the schema did not exist.

- Provide clients with constraint violation details as separate fields (Pavel Stehule)

This allows clients to retrieve table, column, data type, or constraint name error details. Previously such information had to be extracted from error strings. Client library support is required to access these fields.

##### **E.81.3.4.1. ALTER**

- Support `IF NOT EXISTS` option in `ALTER TYPE ... ADD VALUE` (Andrew Dunstan)

This is useful for conditionally adding values to enumerated types.

- Add `ALTER ROLE ALL SET` to establish settings for all users (Peter Eisentraut)

This allows settings to apply to all users in all databases. `ALTER DATABASE SET` already allowed addition of settings for all users in a single database. `postgresql.conf` has a similar effect.

- Add support for `ALTER RULE ... RENAME` (Ali Dar)

##### **E.81.3.4.2. VIEWS**

- Add materialized views (Kevin Grittner)

Unlike ordinary views, where the base tables are read on every access, materialized views create physical tables at creation or refresh time. Access to the materialized view then reads from its physical table. There is not yet any facility for incrementally refreshing materialized views or auto-accessing them via base table access.

- Make simple views auto-updatable (Dean Rasheed)

Simple views that reference some or all columns from a single base table are now updatable by default. More complex views can be made updatable using `INSTEAD OF` triggers or `INSTEAD` rules.

- Add `CREATE RECURSIVE VIEW` syntax (Peter Eisentraut)

Internally this is translated into `CREATE VIEW ... WITH RECURSIVE ...`.

- Improve view/rule printing code to handle cases where referenced tables are renamed, or columns are renamed, added, or dropped (Tom Lane)

Table and column renamings can produce cases where, if we merely substitute the new name into the original text of a rule or view, the result is ambiguous. This change fixes the rule-dumping code to insert manufactured table and column aliases when needed to preserve the original semantics.

### E.81.3.5. Data Types

- Increase the maximum size of large objects from 2GB to 4TB (Nozomi Anzai, Yugo Nagata)

This change includes adding 64-bit-capable large object access functions, both in the server and in `libpq`.

- Allow text timezone designations, e.g. “America/Chicago”, in the “T” field of ISO-format `timestamptz` input (Bruce Momjian)

#### E.81.3.5.1. JSON

- Add operators and functions to extract elements from `JSON` values (Andrew Dunstan)
- Allow `JSON` values to be converted into records (Andrew Dunstan)
- Add functions to convert scalars, records, and `hstore` values to `JSON` (Andrew Dunstan)

### E.81.3.6. Functions

- Add `array_remove()` and `array_replace()` functions (Marco Nenciarini, Gabriele Bartolini)
- Allow `concat()` and `format()` to properly expand `VARIADIC`-labeled arguments (Pavel Stehule)
- Improve `format()` to provide field width and left/right alignment options (Pavel Stehule)
- Make `to_char()`, `to_date()`, and `to_timestamp()` handle negative (BC) century values properly (Bruce Momjian)

Previously the behavior was either wrong or inconsistent with positive/AD handling, e.g. with the format mask “IYYY-IW-DY”.

- Make `to_date()` and `to_timestamp()` return proper results when mixing ISO and Gregorian week/day designations (Bruce Momjian)
- Cause `pg_get_viewdef()` to start a new line by default after each `SELECT` target list entry and `FROM` entry (Marko Tiikkaja)

This reduces line length in view printing, for instance in `pg_dump` output.

- Fix `map_sql_value_to_xml_value()` to print values of domain types the same way their base type would be printed (Pavel Stehule)

There are special formatting rules for certain built-in types such as `boolean`; these rules now also apply to domains over these types.

### E.81.3.7. Server-Side Languages

#### E.81.3.7.1. PL/pgSQL Server-Side Language

- Allow PL/pgSQL to use `RETURN` with a composite-type expression (Asif Rehman)

Previously, in a function returning a composite type, `RETURN` could only reference a variable of that type.

- Allow PL/pgSQL to access constraint violation details as separate fields (Pavel Stehule)

- Allow PL/pgSQL to access the number of rows processed by `COPY` (Pavel Stehule)

A `COPY` executed in a PL/pgSQL function now updates the value retrieved by `GET DIAGNOSTICS x = ROW_COUNT`.

- Allow unreserved keywords to be used as identifiers everywhere in PL/pgSQL (Tom Lane)

In certain places in the PL/pgSQL grammar, keywords had to be quoted to be used as identifiers, even if they were nominally unreserved.

#### **E.81.3.7.2. PL/Python Server-Side Language**

- Add PL/Python result object string handler (Peter Eisentraut)

This allows `plpy.debug(rv)` to output something reasonable.

- Make PL/Python convert OID values to a proper Python numeric type (Peter Eisentraut)
- Handle SPI errors raised explicitly (with PL/Python's `RAISE`) the same as internal SPI errors (Oskari Saarenmaa and Jan Urbanski)

#### **E.81.3.8. Server Programming Interface (SPI)**

- Prevent leakage of SPI tuple tables during subtransaction abort (Tom Lane)

At the end of any failed subtransaction, the core SPI code now releases any SPI tuple tables that were created during that subtransaction. This avoids the need for SPI-using code to keep track of such tuple tables and release them manually in error-recovery code. Failure to do so caused a number of transaction-lifespan memory leakage issues in PL/pgSQL and perhaps other SPI clients. `SPI_freetuptable()` now protects itself against multiple freeing requests, so any existing code that did take care to clean up shouldn't be broken by this change.

- Allow SPI functions to access the number of rows processed by `COPY` (Pavel Stehule)

#### **E.81.3.9. Client Applications**

- Add command-line utility `pg_isready` to check if the server is ready to accept connections (Phil Sorber)
- Support multiple `--table` arguments for `pg_restore`, `clusterdb`, `reindexdb`, and `vacuumdb` (Josh Kuipersmidt)

This is similar to the way `pg_dump`'s `--table` option works.

- Add `--dbname` option to `pg_dumpall`, `pg_basebackup`, and `pg_receivexlog` to allow specifying a connection string (Amit Kapila)
- Add `libpq` function `PQconninfo()` to return connection information (Zoltán Böszörményi, Magnus Hagander)

##### **E.81.3.9.1. psql**

- Adjust function cost settings so `psql` tab completion and pattern searching are more efficient (Tom Lane)
- Improve `psql`'s tab completion coverage (Jeff Janes, Dean Rasheed, Peter Eisentraut, Magnus Hagander)
- Allow the `psql --single-transaction` mode to work when reading from standard input (Fabien Coelho, Robert Haas)

Previously this option only worked when reading from a file.

- Remove `psql` warning when connecting to an older server (Peter Eisentraut)

A warning is still issued when connecting to a server of a newer major version than `psql`'s.

**E.81.3.9.1.1. Backslash Commands**

- Add `psql` command `\watch` to repeatedly execute a SQL command (Will Leinweber)
- Add `psql` command `\gset` to store query results in `psql` variables (Pavel Stehule)
- Add SSL information to `psql`'s `\conninfo` command (Alastair Turner)
- Add “Security” column to `psql`'s `\df+` output (Jon Erdman)
- Allow `psql` command `\l` to accept a database name pattern (Peter Eisentraut)
- In `psql`, do not allow `\connect` to use defaults if there is no active connection (Bruce Momjian)  
This might be the case if the server had crashed.
- Properly reset state after failure of a SQL command executed with `psql`'s `\g file` (Tom Lane)

Previously, the output from subsequent SQL commands would unexpectedly continue to go to the same file.

**E.81.3.9.1.2. Output**

- Add a `latex-longtable` output format to `psql` (Bruce Momjian)  
This format allows tables to span multiple pages.
- Add a `border=3` output mode to the `psql latex` format (Bruce Momjian)
- In `psql`'s tuples-only and expanded output modes, no longer emit “(No rows)” for zero rows (Peter Eisentraut)
- In `psql`'s unaligned, expanded output mode, no longer print an empty line for zero rows (Peter Eisentraut)

**E.81.3.9.2. pg\_dump**

- Add `pg_dump --jobs` option to dump tables in parallel (Joachim Wieland)
- Make `pg_dump` output functions in a more predictable order (Joel Jacobson)
- Fix tar files emitted by `pg_dump` to be POSIX conformant (Brian Weaver, Tom Lane)
- Add `--dbname` option to `pg_dump`, for consistency with other client commands (Heikki Linnakangas)

The database name could already be supplied last without a flag.

**E.81.3.9.3. initdb**

- Make `initdb fsync` the newly created data directory (Jeff Davis)

This insures data integrity in event of a system crash shortly after `initdb`. This can be disabled by using `--nosync`.

- Add `initdb --sync-only` option to sync the data directory to durable storage (Bruce Momjian)

This is used by `pg_upgrade`.

- Make `initdb` issue a warning about placing the data directory at the top of a file system mount point (Bruce Momjian)

**E.81.3.10. Source Code**

- Add infrastructure to allow plug-in background worker processes (Álvaro Herrera)
- Create a centralized timeout API (Zoltán Böszörményi)
- Create `libpgcommon` and move `pg_malloc()` and other functions there (Álvaro Herrera, Andres Freund)

This allows `libpgport` to be used solely for portability-related code.

- Add support for list links embedded in larger structs (Andres Freund)
- Use `SA_RESTART` for all signals, including `SIGALRM` (Tom Lane)
- Ensure that the correct text domain is used when translating `errcontext()` messages (Heikki Linnakangas)
- Standardize naming of client-side memory allocation functions (Tom Lane)
- Provide support for “static assertions” that will fail at compile time if some compile-time-constant condition is not met (Andres Freund, Tom Lane)
- Support `Assert()` in client-side code (Andrew Dunstan)
- Add decoration to inform the C compiler that some `ereport()` and `elog()` calls do not return (Peter Eisentraut, Andres Freund, Tom Lane, Heikki Linnakangas)
- Allow options to be passed to the regression test output comparison utility via `PG_REGRESS_DIFF_OPTS` (Peter Eisentraut)
- Add isolation tests for `CREATE INDEX CONCURRENTLY` (Abhijit Menon-Sen)
- Remove typedefs for `int2/int4` as they are better represented as `int16/int32` (Peter Eisentraut)
- Fix `install-strip` on Mac OS X (Peter Eisentraut)
- Remove configure flag `--disable-shared`, as it is no longer supported (Bruce Momjian)
- Rewrite `pgindent` in Perl (Andrew Dunstan)
- Provide Emacs macro to set Perl formatting to match PostgreSQL's `perltidy` settings (Peter Eisentraut)
- Run tool to check the keyword list whenever the backend grammar is changed (Tom Lane)
- Change the way `UESCAPE` is lexed, to significantly reduce the size of the lexer tables (Heikki Linnakangas)
- Centralize flex and bison make rules (Peter Eisentraut)

This is useful for `pgxs` authors.

- Change many internal backend functions to return object `OIDS` rather than `void` (Dimitri Fontaine)

This is useful for event triggers.

- Invent `pre-commit/pre-prepare/pre-subcommit` events for transaction callbacks (Tom Lane)

Loadable modules that use transaction callbacks might need modification to handle these new event types.

- Add function `pg_identify_object()` to produce a machine-readable description of a database object (Álvaro Herrera)
- Add `post-ALTER-object` server hooks (KaiGai Kohei)
- Implement a generic binary heap and use it for Merge-Append operations (Abhijit Menon-Sen)
- Provide a tool to help detect timezone abbreviation changes when updating the `src/timezone/data` files (Tom Lane)
- Add `pkg-config` support for `libpq` and `ecpg` libraries (Peter Eisentraut)
- Remove `src/tools/backend`, now that the content is on the PostgreSQL wiki (Bruce Momjian)
- Split out WAL reading as an independent facility (Heikki Linnakangas, Andres Freund)
- Use a 64-bit integer to represent WAL positions (`XLogRecPtr`) instead of two 32-bit integers (Heikki Linnakangas)

Generally, tools that need to read the WAL format will need to be adjusted.

- Allow PL/Python to support platform-specific include directories (Peter Eisentraut)
- Allow PL/Python on OS X to build against custom versions of Python (Peter Eisentraut)

### **E.81.3.11. Additional Modules**

- Add a Postgres foreign data wrapper contrib module to allow access to other Postgres servers (Shigeru Hanada)

This foreign data wrapper supports writes.

- Add `pg_xlogdump` contrib program (Andres Freund)
- Add support for indexing of regular-expression searches in `pg_trgm` (Alexander Korotkov)
- Improve `pg_trgm`'s handling of multibyte characters (Tom Lane)

On a platform that does not have the `wcstombs()` or `towlower()` library functions, this could result in an incompatible change in the contents of `pg_trgm` indexes for non-ASCII data. In such cases, `REINDEX` those indexes to ensure correct search results.

- Add a `pgstattuple` function to report the size of the pending-insertions list of a GIN index (Fujii Masao)
- Make `oid2name`, `pgbench`, and `vacuumlo` set `fallback_application_name` (Amit Kapila)
- Improve output of `pg_test_timing` (Bruce Momjian)
- Improve output of `pg_test_fsync` (Peter Geoghegan)
- Create a dedicated foreign data wrapper, with its own option validator function, for `dblink` (Shigeru Hanada)

When using this FDW to define the target of a `dblink` connection, instead of using a hard-wired list of connection options, the underlying `libpq` library is consulted to see what connection options it supports.

#### **E.81.3.11.1. `pg_upgrade`**

- Allow `pg_upgrade` to do dumps and restores in parallel (Bruce Momjian, Andrew Dunstan)

This allows parallel schema dump/restore of databases, as well as parallel copy/link of data files per tablespace. Use the `--jobs` option to specify the level of parallelism.

- Make `pg_upgrade` create Unix-domain sockets in the current directory (Bruce Momjian, Tom Lane)

This reduces the possibility that someone will accidentally connect during the upgrade.

- Make `pg_upgrade --check` mode properly detect the location of non-default socket directories (Bruce Momjian, Tom Lane)
- Improve performance of `pg_upgrade` for databases with many tables (Bruce Momjian)
- Improve `pg_upgrade`'s logs by showing executed commands (Álvaro Herrera)
- Improve `pg_upgrade`'s status display during copy/link (Bruce Momjian)

#### **E.81.3.11.2. `pgbench`**

- Add `--foreign-keys` option to `pgbench` (Jeff Janes)

This adds foreign key constraints to the standard tables created by `pgbench`, for use in foreign key performance testing.

- Allow `pgbench` to aggregate performance statistics and produce output every `--aggregate-interval` seconds (Tomas Vondra)

- Add `pgbench --sampling-rate` option to control the percentage of transactions logged (Tomas Vondra)
- Reduce and improve the status message output of `pgbench`'s initialization mode (Robert Haas, Peter Eisentraut)
- Add `pgbench -q` mode to print one output line every five seconds (Tomas Vondra)
- Output `pgbench` elapsed and estimated remaining time during initialization (Tomas Vondra)
- Allow `pgbench` to use much larger scale factors, by changing relevant columns from `integer` to `bigint` when the requested scale factor exceeds 20000 (Greg Smith)

### E.81.3.12. Documentation

- Allow EPUB-format documentation to be created (Peter Eisentraut)
- Update FreeBSD kernel configuration documentation (Brad Davis)
- Improve `WINDOW` function documentation (Bruce Momjian, Florian Pflug)
- Add instructions for setting up the documentation tool chain on macOS (Peter Eisentraut)
- Improve `commit_delay` documentation (Peter Geoghegan)

## E.82. Release 9.2.24

**Release date:** 2017-11-09

This release contains a variety of fixes from 9.2.23. For information about new features in the 9.2 major release, see Section E.106.

This is expected to be the last PostgreSQL release in the 9.2.X series. Users are encouraged to update to a newer release branch soon.

### E.82.1. Migration to Version 9.2.24

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.22, see Section E.84.

### E.82.2. Changes

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)
- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)

The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range's subtype has hash support. This does not affect any of the built-in range types, since they're all hashable anyway.

- Fix low-probability loss of `NOTIFY` messages due to XID wraparound (Marko Tiikkaja, Tom Lane)

If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Correctly restore the `umask` setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentraut)
- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)
- Fix `libpq` to not require user's home directory to exist (Tom Lane)

In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.

- Fix `libpq` to guard against integer overflow in the row count of a `PGresult` (Michael Paquier)
- Sync our copy of the timezone library with IANA release `tzcode2017c` (Tom Lane)

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to `tzdata` release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

## E.83. Release 9.2.23

**Release date:** 2017-08-31

This release contains a small number of fixes from 9.2.22. For information about new features in the 9.2 major release, see Section E.106.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

### E.83.1. Migration to Version 9.2.23

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.22, see Section E.84.

### E.83.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

All other relevant `information_schema` views include foreign tables, but this one ignored them.

Since this view definition is installed by `initdb`, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in `psql`:

```
SET search_path TO information_schema;  
CREATE OR REPLACE VIEW table_privileges AS
```

```

SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
       CAST(grantee.rolname AS sql_identifier) AS grantee,
       CAST(current_database() AS sql_identifier) AS table_catalog,
       CAST(nc.nspname AS sql_identifier) AS table_schema,
       CAST(c.relname AS sql_identifier) AS table_name,
       CAST(c.prtype AS character_data) AS privilege_type,
       CAST(
         CASE WHEN
           -- object owner always has grant options
           pg_has_role(grantee.oid, c.relowner, 'USAGE')
           OR c.grantable
           THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
       CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no)
AS with_hierarchy

FROM (
  SELECT oid, relname, relnamespace, relkind, relowner,
 (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
 ) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee,
 prtype, grantable),
 pg_namespace nc,
 pg_authid u_grantor,
 (
  SELECT oid, rolname FROM pg_authid
  UNION ALL
  SELECT 0::oid, 'PUBLIC'
 ) AS grantee (oid, rolname)

WHERE c.relnamespace = nc.oid
      AND c.relkind IN ('r', 'v', 'f')
      AND c.grantee = grantee.oid
      AND c.grantor = u_grantor.oid
      AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE',
 'REFERENCES', 'TRIGGER')
      AND (pg_has_role(u_grantor.oid, 'USAGE')
           OR pg_has_role(grantee.oid, 'USAGE')
           OR grantee.rolname = 'PUBLIC');

```

This must be repeated in each database to be fixed, including `template0`.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)

This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Change ecpg's parser to allow RETURNING clauses without attached C variables (Michael Meskes)

This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T` is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.

## E.84. Release 9.2.22

**Release date:** 2017-08-10

This release contains a variety of fixes from 9.2.21. For information about new features in the 9.2 major release, see Section E.106.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

### E.84.1. Migration to Version 9.2.22

A dump/restore is not required for those running 9.2.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.2.20, see Section E.86.

### E.84.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you'll still need a restart.)
2. In *each* database of the cluster, run the following commands as superuser:

```
SET search_path = pg_catalog;
CREATE OR REPLACE VIEW pg_user_mappings AS
SELECT
    U.oid          AS umid,
    S.oid          AS srvid,
    S.srvname     AS srvname,
    U.umuser      AS umuser,
    CASE WHEN U.umuser = 0 THEN
        'public'
    ELSE
        A.rolname
    END AS username,
    CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
              AND (pg_has_role(S.srvowner, 'USAGE'))
```

```

        OR has_server_privilege(S.oid, 'USAGE'))
    OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
    OR (SELECT rolsuper FROM pg_authid WHERE rolname =
current_user)
        THEN U.umoptions
    ELSE NULL END AS umoptions
FROM pg_user_mapping U
    LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
    pg_foreign_server S ON (U.umserver = S.oid);

```

3. Do not forget to include the `template0` and `template1` databases, or the vulnerability will still exist in databases you create later. To fix `template0`, you'll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
```

and then after fixing `template0`, undo that with

```
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
```

In prior versions, instead use

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

4. Finally, remove the `allow_system_table_mods` configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)

`libpq` ignores empty password specifications, and does not transmit them to the server. So, if a user's password has been set to the empty string, it's impossible to log in with that password via `psql` or other `libpq`-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-`libpq`-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, `md5`, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)

This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)
- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)
- Prevent sending SSL session tickets to clients (Tom Lane)

This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting `tcp_keepalives_idle` on Solaris (Tom Lane)
- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)

Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector's receive buffer size is at least 100KB (Tom Lane)

This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an `XLOG_SWITCH` WAL record (Andres Freund)
- Fix `SIGHUP` and `SIGUSR1` handling in walsender processes (Petr Jelinek, Andres Freund)
- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)
- Fix cases where an `INSERT` or `UPDATE` assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
- Move autogenerated array types out of the way during `ALTER ... RENAME` (Vik Fearing)

Previously, we would rename a conflicting autogenerated array type out of the way during `CREATE`; this fix extends that behavior to renaming operations.

- Ensure that `ALTER USER ... SET` accepts all the syntax variants that `ALTER ROLE ... SET` does (Peter Eisentraut)
- Properly update dependency info when changing a datatype I/O function's argument or return type from `opaque` to the correct type (Heikki Linnakangas)

`CREATE TYPE` updates I/O functions declared in this long-obsolete style, but it forgot to record a dependency on the type, allowing a subsequent `DROP TYPE` to leave broken function definitions behind.

- Reduce memory usage when `ANALYZE` processes a `tsvector` column (Heikki Linnakangas)
- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing `money` values by integers or floats (Tom Lane)
- Tighten checks for whitespace in functions that parse identifiers, such as `regprocedurein()` (Tom Lane)

Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant `#define` symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)

This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In `psql`, fix failure when `COPY FROM STDIN` is ended with a keyboard EOF signal and then another `COPY FROM STDIN` is attempted (Thomas Munro)

This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix `pg_dump` to not emit invalid SQL for an empty operator class (Daniel Gustafsson)
- Fix `pg_dump` output to stdout on Windows (Kuntal Ghosh)

A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)

In some corner cases, `pg_dump` relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.

- Fix dumping of function expressions in the `FROM` clause in cases where the expression does not parse into something that looks like a function call (Tom Lane)
- Fix `pg_basebackup` output to stdout on Windows (Haribabu Kommi)

A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

- Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)

This condition could prevent upgraded standby servers from reconnecting.

- Always use `-fPIC`, not `-fpic`, when building shared libraries with `gcc` (Tom Lane)

This supports larger extension libraries on platforms where it makes a difference.

- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the `openssl` library is not within a `vc` subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for `libxml2` header files (Andrew Dunstan)

This fixes a former need to move things around in standard Windows installations of `libxml2`.

- In MSVC builds, recognize a Tcl library that is named `tc186.lib` (Noah Misch)

## E.85. Release 9.2.21

**Release date:** 2017-05-11

This release contains a variety of fixes from 9.2.20. For information about new features in the 9.2 major release, see Section E.106.

The PostgreSQL community will stop releasing updates for the 9.2.X release series in September 2017. Users are encouraged to update to a newer release branch soon.

### E.85.1. Migration to Version 9.2.21

A dump/restore is not required for those running 9.2.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.2.20, see Section E.86.

### E.85.2. Changes

- Restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

The previous coding allowed the owner of a foreign server object, or anyone he has granted server `USAGE` permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of `information_schema.user_mapping_options`, namely that these options are visible to the user being mapped, or if the mapping is for `PUBLIC` and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb'd databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.84.

- Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from `pg_statistic`, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator's implementation function is not certified leak-proof and the calling user does not have

permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

- Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)

This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

- Fix incorrect reconstruction of `pg_subtrans` entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)

In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in `pg_subtrans`, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)

Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)

The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)

This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gieth)

This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
- Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)

Previously it failed to produce a wrapping `<table>` element.

- Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)
- Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)

Neither of these system calls are likely to fail in typical situations, but if they did, `fd.c` could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)

This could result in attempting to write to the event log when that isn't accessible, so that no logging happens at all.

- Fix `ecpg` to support `COMMIT PREPARED` and `ROLLBACK PREPARED` (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in `ecpg` (Michael Meskes)

- In `pg_dump`, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)

In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

- Avoid emitting an invalid list file in `pg_restore -l` when SQL object names contain newlines (Tom Lane)

Replace newlines by spaces, which is sufficient to make the output valid for `pg_restore -L`'s purposes.

- Fix `pg_upgrade` to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)

Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in `contrib/adminpack`'s `pg_file_write()` function (Noah Misch)

Notably, it failed to detect errors reported by `fclose()`.

- In `contrib/dblink`, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Support OpenSSL 1.1.0 (Heikki Linnakangas, Andreas Karlsson, Tom Lane)

This is a back-patch of work previously done in newer branches; it's needed since many platforms are adopting newer OpenSSL versions.

- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release `tzcode2017b` (Tom Lane)

This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to `tzdata` release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

The Microsoft MSVC build scripts neglected to install the `posixrules` file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the `US/Eastern` zone. If you don't want that, remove the `posixrules` file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

## E.86. Release 9.2.20

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.2.19. For information about new features in the 9.2 major release, see Section E.106.

## E.86.1. Migration to Version 9.2.20

A dump/restore is not required for those running 9.2.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

## E.86.2. Changes

- Fix a race condition that could cause indexes built with `CREATE INDEX CONCURRENTLY` to be corrupt (Pavan Deolasee, Tom Lane)

If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)

Previously, this was skipped when `wal_level = minimal`, but actually it's necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Fix WAL page header validation when re-reading segments (Takayuki Tsunakawa, Amit Kapila)

In corner cases, a spurious “out-of-sequence TLI” error could be reported during recovery.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)
- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)
- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)

This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)

Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure `ALTER TABLE` preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)

Previously, non-default settings of `default_tablespace` could result in broken indexes.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)

This avoids “could not find trigger *NNN*” or “relation *NNN* has no triggers” errors.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via `ALTER TABLE ... INHERIT` (Amit Langote)

The OID column should be treated the same as regular user columns in this case, but it wasn't, leading to odd behavior in later inheritance changes.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concur-

rent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)

This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don't share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)

Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)

Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)
- Fix performance problems in `ts_rewrite()` (Tom Lane)
- Fix `ts_rewrite()`'s handling of nested NOT operators (Tom Lane)
- Fix `array_fill()` to handle empty arrays properly (Tom Lane)
- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)

The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)

This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Avoid discarding `interval-to-interval` casts that aren't really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order `interval` fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

- Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)
- Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)
- Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)

This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

- Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)

This matches the (previously undocumented) behavior of PL/Tcl's `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn't a real column named that.

- Allow DOS-style line endings in `~/pgpass` files, even on Unix (Vik Fearing)

This change simplifies use of the same password file across Unix and Windows machines.

- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)

- Fix `psql`'s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)

Previously, such a setting caused output intended for the pager to vanish entirely.

- Improve `contrib/dblink`'s reporting of low-level `libpq` errors, such as out-of-memory (Joe Conway)
- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release `tzcode2016j` (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn't support hard links.

- Update time zone data files to `tzdata` release 2016j for DST law changes in northern Cyprus (adding a new zone `Asia/Famagusta`), Russia (adding a new zone `Europe/Saratov`), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

## E.87. Release 9.2.19

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.2.18. For information about new features in the 9.2 major release, see Section E.106.

### E.87.1. Migration to Version 9.2.19

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

### E.87.2. Changes

- Fix `EvalPlanQual` rechecks involving CTE scans (Tom Lane)

The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierrth)

The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix `EXPLAIN` to emit valid XML when `track_io_timing` is on (Markus Winand)

Previously the XML output-format option produced syntactically invalid tags such as `<I/O-Read-Time>`. That is now rendered as `<I-O-Read-Time>`.

- Suppress printing of zeroes for unmeasured times in `EXPLAIN` (Maksim Milyutin)

Certain option combinations resulted in printing zero values for times that actually aren't ever measured in that combination. Our general policy in `EXPLAIN` is not to print such fields at all, so do that consistently in all cases.

- Fix timeout length when `VACUUM` is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing `VACUUM` to give up on truncation much more easily than intended. Set it to the intended value.

- Fix bugs in merging inherited `CHECK` constraints while creating or altering a table (Tom Lane, Amit Langote)

Allow identical `CHECK` constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a `NOT VALID` constraint on the child. Likewise, prevent merging of a `NO INHERIT` child constraint with an inherited constraint.

- Remove artificial restrictions on the values accepted by `numeric_in()` and `numeric_recv()` (Tom Lane)

We allow numeric values up to the limit of the storage format (more than  $1e100000$ ), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
- Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)

This can't do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn't designed with this situation in mind.

- Don't try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

- Make `ecpg's --help` and `--version` options work consistently with our other executables (Haribabu Kommi)
- In `pg_dump`, never dump range constructor functions (Tom Lane)

This oversight led to `pg_upgrade` failures with extensions containing range types, due to duplicate creation of the constructor functions.

- Fix `contrib/intarray/bench/bench.pl` to print the results of the `EXPLAIN` it does when given the `-e` option (Daniel Gustafsson)
- Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in `tzdata` release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbrevs` view to fail altogether.

- Update time zone data files to `tzdata` release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, `AMT` is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the `Default` abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

## E.88. Release 9.2.18

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.2.17. For information about new features in the 9.2 major release, see Section E.106.

### E.88.1. Migration to Version 9.2.18

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

### E.88.2. Changes

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function's body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs' handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in `vacuumdb` and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a `conninfo` string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in `psql`'s `\connect` and `\password` commands to match the documentation.

Introduce a new `-reuse-previous` option in `psql`'s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a `conninfo` string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

`pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that `IS NULL` should return `TRUE` for a row of all null values (thus `ROW(NULL, NULL) IS NULL` yields `TRUE`), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL, NULL)) IS NULL` yields `FALSE`). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing `TRUE` in both cases), and `contrib/postgres_fdw` could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)

- Prevent crash in `close_ps()` (the `point ## lseg` operator) for NaN input coordinates (Tom Lane)

Make it return NULL instead of crashing.

- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)
- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

Some cases in `VACUUM` unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during `VACUUM FREEZE` (Simon Riggs, Álvaro Herrera)

`VACUUM FREEZE` on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- When a manual `ANALYZE` specifies a column list, don't reset the table's `changes_since_analyze` counter (Tom Lane)

If we're only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix `ANALYZE`'s overestimation of `n_distinct` for a unique or nearly-unique column with many null entries (Tom Lane)

The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

Normally this isn't much of a problem because the vacuum doesn't take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
- Fix `contrib/btree_gin` to handle the smallest possible `bigint` value correctly (Peter Eisentraut)
- Teach `libpq` to correctly decode server version from future servers (Peter Eisentraut)

It's planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that `PQserverVersion()` returns the correct value for such cases.

- Fix `ecpg`'s code for `unsigned long long` array elements (Michael Meskes)
- In `pg_dump` with both `-c` and `-C` options, avoid emitting an unwanted `CREATE SCHEMA public` command (David Johnston, Tom Lane)
- Make `pg_basebackup` accept `-z 0` as specifying no compression (Fujii Masao)

- Fix makefiles' rule for building AIX shared libraries to be safe for parallel make (Noah Misch)
- Fix TAP tests and MSVC scripts to work when build directory's path name contains spaces (Michael Paquier, Kyotaro Horiguchi)
- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA's tzcode release 2016c (Tom Lane)

This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

## E.89. Release 9.2.17

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.2.16. For information about new features in the 9.2 major release, see Section E.106.

### E.89.1. Migration to Version 9.2.17

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

### E.89.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it's clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It's possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any *N*-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)
- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

Given a three-or-more-way equivalence class of variables, such as  $X.X = Y.Y = Z.Z$ , it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn't satisfy the `WHERE` clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix possible misbehavior of `TH`, `th`, and `Y,YYY` format codes in `to_timestamp()` (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the `array` argument of a `value operator ANY (array)` construct is a sub-SELECT (Tom Lane)
- Make `pg_regress` use a startup timeout from the `PGCTLTIMEOUT` environment variable, if that's set (Tom Lane)

This is for consistency with a behavior recently added to `pg_ctl`; it eases automated testing on slow machines.

- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.

- Back-port 9.4-era memory-barrier code changes into 9.2 and 9.3 (Tom Lane)

These changes were not originally needed in pre-9.4 branches, but we recently back-patched a fix that expected the barrier code to work properly. Only IA64 (when using `icc`), HPPA, and Alpha platforms are affected.

- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks` (Tom Lane)
- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Avoid possibly-unsafe use of Windows' `FormatMessage()` function (Christian Ullrich)

Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to tzdata release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

## E.90. Release 9.2.16

**Release date:** 2016-03-31

This release contains a variety of fixes from 9.2.15. For information about new features in the 9.2 major release, see Section E.106.

### E.90.1. Migration to Version 9.2.16

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

### E.90.2. Changes

- Fix incorrect handling of NULL index entries in indexed `ROW()` comparisons (Tom Lane)

An index search using a row comparison such as `ROW(a, b) > ROW('x', 'y')` would stop upon reaching a NULL entry in the `b` column, ignoring the fact that there might be non-NULL `b` values associated with later values of `a`.

- Avoid unlikely data-loss scenarios due to renaming files without adequate `fsync()` calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)
- Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
- Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
- Fix parsing of affix files for `ispell` dictionaries (Tom Lane)

The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example `ı` in Turkish UTF8 locales.

- Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)

This dodges a portability problem on FreeBSD-derived platforms (including macOS).

- Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a Postgres build done with Visual Studio 2013 (Christian Ullrich)

This is a workaround for a bug in Visual Studio 2013's runtime library, which Microsoft have stated they will not fix in that version.

- Fix `psql`'s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)
- Fix `psql`'s tab completion for `SECURITY LABEL` (Tom Lane)

Pressing TAB after `SECURITY LABEL` might cause a crash or offering of inappropriate keywords.

- Make `pg_ctl` accept a wait timeout from the `PGCLTIMEOUT` environment variable, if none is specified on the command line (Noah Misch)

This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.

- Fix incorrect test for Windows service status in `pg_ctl` (Manuel Mathar)

The previous set of minor releases attempted to fix `pg_ctl` to properly determine whether to send log messages to Window's Event Log, but got the test backwards.

- Fix `pgbench` to correctly handle the combination of `-C` and `-M prepared` options (Tom Lane)
- In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
- Make PL/Python cope with function names that aren't valid Python identifiers (Jim Nasby)
- Fix multiple mistakes in the statistics returned by `contrib/pgstattuple`'s `pgstatindex()` function (Tom Lane)
- Remove dependency on `psed` in MSVC builds, since it's no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to `tzdata` release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

## E.91. Release 9.2.15

**Release date:** 2016-02-11

This release contains a variety of fixes from 9.2.14. For information about new features in the 9.2 major release, see Section E.106.

### E.91.1. Migration to Version 9.2.15

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

### E.91.2. Changes

- Fix infinite loops and buffer-overflow problems in regular expressions (Tom Lane)

Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- Perform an immediate shutdown if the `postmaster.pid` file is removed (Tom Lane)

The postmaster now checks every minute or so that `postmaster.pid` is still there and still contains its own PID. If not, it performs an immediate shutdown, as though it had received SIGQUIT. The main motivation for this change is to ensure that failed buildfarm runs will get cleaned up without manual intervention; but it also serves to limit the bad effects if a DBA forcibly removes `postmaster.pid` and then starts a new postmaster.

- In `SERIALIZABLE` transaction isolation mode, serialization anomalies could be missed due to race conditions during insertions (Kevin Grittner, Thomas Munro)
- Fix failure to emit appropriate WAL records when doing `ALTER TABLE ... SET TABLESPACE` for unlogged relations (Michael Paquier, Andres Freund)

Even though the relation's data is unlogged, the move must be logged or the relation will be inaccessible after a standby is promoted to master.

- Fix possible misinitialization of unlogged relations at the end of crash recovery (Andres Freund, Michael Paquier)
- Fix `ALTER COLUMN TYPE` to reconstruct inherited check constraints properly (Tom Lane)
- Fix `REASSIGN OWNED` to change ownership of composite types properly (Álvaro Herrera)
- Fix `REASSIGN OWNED` and `ALTER OWNER` to correctly update granted-permissions lists when changing owners of data types, foreign data wrappers, or foreign servers (Bruce Momjian, Álvaro Herrera)
- Fix `REASSIGN OWNED` to ignore foreign user mappings, rather than fail (Álvaro Herrera)
- Add more defenses against bad planner cost estimates for GIN index scans when the index's internal statistics are very out-of-date (Tom Lane)
- Make planner cope with hypothetical GIN indexes suggested by an index advisor plug-in (Julien Rouhaud)
- Fix dumping of whole-row Vars in `ROW()` and `VALUES()` lists (Tom Lane)
- Fix possible internal overflow in numeric division (Dean Rasheed)
- Fix enforcement of restrictions inside parentheses within regular expression lookahead constraints (Tom Lane)

Lookahead constraints aren't allowed to contain backrefs, and parentheses within them are always considered non-capturing, according to the manual. However, the code failed to handle these cases properly inside a parenthesized subexpression, and would give unexpected results.

- Conversion of regular expressions to indexscan bounds could produce incorrect bounds from regexps containing lookahead constraints (Tom Lane)
- Fix regular-expression compiler to handle loops of constraint arcs (Tom Lane)

The code added for CVE-2007-4772 was both incomplete, in that it didn't handle loops involving more than one state, and incorrect, in that it could cause assertion failures (though there seem to be no bad consequences of that in a non-assert build). Multi-state loops would cause the compiler to run until the query was canceled or it reached the too-many-states error condition.

- Improve memory-usage accounting in regular-expression compiler (Tom Lane)

This causes the code to emit “regular expression is too complex” errors in some cases that previously used unreasonable amounts of time and memory.

- Improve performance of regular-expression compiler (Tom Lane)
- Make `%h` and `%r` escapes in `log_line_prefix` work for messages emitted due to `log_connections` (Tom Lane)

Previously, `%h/%r` started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

- On Windows, ensure the shared-memory mapping handle gets closed in child processes that don't need it (Tom Lane, Amit Kapila)

This oversight resulted in failure to recover from crashes whenever `logging_collector` is turned on.

- Fix possible failure to detect socket EOF in non-blocking mode on Windows (Tom Lane)

It's not entirely clear whether this problem can happen in pre-9.5 branches, but if it did, the symptom would be that a walsender process would wait indefinitely rather than noticing a loss of connection.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)
- In `psql`, ensure that `libreadline`'s idea of the screen size is updated when the terminal window size changes (Merlin Moncure)

Previously, `libreadline` did not notice if the window was resized during query output, leading to strange behavior during later input of multiline queries.

- Fix `psql`'s `\det` command to interpret its pattern argument the same way as other `\d` commands with potentially schema-qualified patterns do (Reece Hart)
- Avoid possible crash in `psql`'s `\c` command when previous connection was via Unix socket and command specifies a new hostname and same username (Tom Lane)
- In `pg_ctl start -w`, test child process status directly rather than relying on heuristics (Tom Lane, Michael Paquier)

Previously, `pg_ctl` relied on an assumption that the new postmaster would always create `postmaster.pid` within five seconds. But that can fail on heavily-loaded systems, causing `pg_ctl` to report incorrectly that the postmaster failed to start.

Except on Windows, this change also means that a `pg_ctl start -w` done immediately after another such command will now reliably fail, whereas previously it would report success if done within two seconds of the first command.

- In `pg_ctl start -w`, don't attempt to use a wildcard listen address to connect to the postmaster (Kondo Yuta)

On Windows, `pg_ctl` would fail to detect postmaster startup if `listen_addresses` is set to `0.0.0.0` or `:::`, because it would try to use that value verbatim as the address to connect to, which doesn't work. Instead assume that `127.0.0.1` or `:::1`, respectively, is the right thing to use.

- In `pg_ctl` on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)
- In `pg_dump` and `pg_basebackup`, adopt the GNU convention for handling tar-archive members exceeding 8GB (Tom Lane)

The POSIX standard for `tar` file format does not allow archive member files to exceed 8GB, but most modern implementations of `tar` support an extension that fixes that. Adopt this extension so that `pg_dump` with `-Ft` no longer fails on tables with more than 8GB of data, and so that `pg_basebackup` can handle files larger than 8GB. In addition, fix some portability issues that could cause failures for members between 4GB and 8GB on some platforms. Potentially these problems could cause unrecoverable data loss due to unreadable backup files.

- Fix assorted corner-case bugs in `pg_dump`'s processing of extension member objects (Tom Lane)
- Make `pg_dump` mark a view's triggers as needing to be processed after its rule, to prevent possible failure during parallel `pg_restore` (Tom Lane)
- Ensure that relation option values are properly quoted in `pg_dump` (Kouhei Sutou, Tom Lane)

A `reloption` value that isn't a simple identifier or number could lead to dump/reload failures due to syntax errors in `CREATE` statements issued by `pg_dump`. This is not an issue with any `reloption`

currently supported by core PostgreSQL, but extensions could allow relocations that cause the problem.

- Fix `pg_upgrade`'s file-copying code to handle errors properly on Windows (Bruce Momjian)
- Install guards in `pgbench` against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)
- Fix failure to localize messages emitted by `pg_receivexlog` and `pg_recvlogical` (Ioseph Kim)
- Avoid dump/reload problems when using both `plpython2` and `plpython3` (Tom Lane)

In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of `libpython` cannot safely be used concurrently). However, `pg_restore` and `pg_upgrade` both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.

- Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
- Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)

This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.

- Improve `libpq`'s handling of out-of-memory situations (Michael Paquier, Amit Kapila, Heikki Linnaakangas)
- Fix order of arguments in `ecpg`-generated `typedef` statements (Michael Meskes)
- Use `%g` not `%f` format in `ecpg`'s `PGTYPESnumeric_from_double()` (Tom Lane)
- Fix `ecpg`-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)

Such a comment is rejected by `ecpg`. It's not yet clear whether `ecpg` itself should be changed.

- Ensure that `contrib/pgcrypto`'s `crypt()` function can be interrupted by query cancel (Andreas Karlsson)
- Accept flex versions later than 2.5.x (Tom Lane, Michael Paquier)

Now that flex 2.6.0 has been released, the version checks in our build scripts needed to be adjusted.

- Install our `missing` script where PGXS builds can find it (Jim Nasby)

This allows sane behavior in a PGXS build done on a machine where build tools such as `bison` are missing.

- Ensure that `dynloader.h` is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
- Add variant regression test expected-output file to match behavior of current `libxml2` (Tom Lane)

The fix for `libxml2`'s CVE-2015-7499 causes it not to output error context reports in some cases where it used to do so. This seems to be a bug, but we'll probably have to live with it for some time, so work around it.

- Update time zone data files to `tzdata` release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

## E.92. Release 9.2.14

**Release date:** 2015-10-08

This release contains a variety of fixes from 9.2.13. For information about new features in the 9.2 major release, see Section E.106.

## E.92.1. Migration to Version 9.2.14

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

## E.92.2. Changes

- Fix `contrib/pgcrypto` to detect and report too-short `crypt()` salts (Josh Kopershmidt)

Certain invalid salt arguments crashed the server or disclosed a few bytes of server memory. We have not ruled out the viability of attacks that arrange for presence of confidential information in the disclosed bytes, but they seem unlikely. (CVE-2015-5288)

- Fix subtransaction cleanup after a portal (cursor) belonging to an outer subtransaction fails (Tom Lane, Michael Paquier)

A function executed in an outer-subtransaction cursor could cause an assertion failure or crash by referencing a relation created within an inner subtransaction.

- Fix insertion of relations into the relation cache “init file” (Tom Lane)

An oversight in a patch in the most recent minor releases caused `pg_trigger_tgrelid_tgname_index` to be omitted from the init file. Subsequent sessions detected this, then deemed the init file to be broken and silently ignored it, resulting in a significant degradation in session startup time. In addition to fixing the bug, install some guards so that any similar future mistake will be more obvious.

- Avoid  $O(N^2)$  behavior when inserting many tuples into a SPI query result (Neil Conway)
- Improve `LISTEN` startup time when there are many unread notifications (Matt Newell)
- Back-patch 9.3-era addition of per-resource-owner lock caches (Jeff Janes)

This substantially improves performance when `pg_dump` tries to dump a large number of tables.

- Disable SSL renegotiation by default (Michael Paquier, Andres Freund)

While use of SSL renegotiation is a good idea in theory, we have seen too many bugs in practice, both in the underlying OpenSSL library and in our usage of it. Renegotiation will be removed entirely in 9.5 and later. In the older branches, just change the default value of `ssl_renegotiation_limit` to zero (disabled).

- Lower the minimum values of the `*_freeze_max_age` parameters (Andres Freund)

This is mainly to make tests of related behavior less time-consuming, but it may also be of value for installations with limited disk space.

- Limit the maximum value of `wal_buffers` to 2GB to avoid server crashes (Josh Berkus)
- Fix rare internal overflow in multiplication of `numeric` values (Dean Rasheed)
- Guard against hard-to-reach stack overflows involving record types, range types, `json`, `jsonb`, `tsquery`, `ltxtquery` and `query_int` (Noah Misch)
- Fix handling of `DOW` and `DOY` in datetime input (Greg Stark)

These tokens aren't meant to be used in datetime values, but previously they resulted in opaque internal error messages rather than “invalid input syntax”.

- Add more query-cancel checks to regular expression matching (Tom Lane)
- Add recursion depth protections to regular expression, `SIMILAR TO`, and `LIKE` matching (Tom Lane)

Suitable search patterns and a low stack depth limit could lead to stack-overflow crashes.

- Fix potential infinite loop in regular expression execution (Tom Lane)

A search pattern that can apparently match a zero-length string, but actually doesn't match because of a back reference, could lead to an infinite loop.

- In regular expression execution, correctly record match data for capturing parentheses within a quantifier even when the match is zero-length (Tom Lane)
- Fix low-memory failures in regular expression compilation (Andreas Seltenreich)
- Fix low-probability memory leak during regular expression execution (Tom Lane)
- Fix rare low-memory failure in lock cleanup during transaction abort (Tom Lane)
- Fix “unexpected out-of-memory situation during sort” errors when using tuplestores with small `work_mem` settings (Tom Lane)
- Fix very-low-probability stack overrun in `qsort` (Tom Lane)
- Fix “invalid memory alloc request size” failure in hash joins with large `work_mem` settings (Tomas Vondra, Tom Lane)
- Fix assorted planner bugs (Tom Lane)

These mistakes could lead to incorrect query plans that would give wrong answers, or to assertion failures in assert-enabled builds, or to odd planner errors such as “could not devise a query plan for the given query”, “could not find pathkey item to sort”, “plan should not reference subplan's variable”, or “failed to assign all NestLoopParams to plan nodes”. Thanks are due to Andreas Seltenreich and Piotr Stefaniak for fuzz testing that exposed these problems.

- Improve planner's performance for `UPDATE/DELETE` on large inheritance sets (Tom Lane, Dean Rasheed)
- Ensure standby promotion trigger files are removed at postmaster startup (Michael Paquier, Fujii Masao)

This prevents unwanted promotion from occurring if these files appear in a database backup that is used to initialize a new standby server.

- During postmaster shutdown, ensure that per-socket lock files are removed and listen sockets are closed before we remove the `postmaster.pid` file (Tom Lane)

This avoids race-condition failures if an external script attempts to start a new postmaster as soon as `pg_ctl stop` returns.

- Fix postmaster's handling of a startup-process crash during crash recovery (Tom Lane)

If, during a crash recovery cycle, the startup process crashes without having restored database consistency, we'd try to launch a new startup process, which typically would just crash again, leading to an infinite loop.

- Do not print a `WARNING` when an autovacuum worker is already gone when we attempt to signal it, and reduce log verbosity for such signals (Tom Lane)
- Prevent autovacuum launcher from sleeping unduly long if the server clock is moved backwards a large amount (Álvaro Herrera)
- Ensure that cleanup of a GIN index's pending-insertions list is interruptible by cancel requests (Jeff Janes)
- Allow all-zeroes pages in GIN indexes to be reused (Heikki Linnakangas)

Such a page might be left behind after a crash.

- Fix handling of all-zeroes pages in SP-GiST indexes (Heikki Linnakangas)

`VACUUM` attempted to recycle such pages, but did so in a way that wasn't crash-safe.

- Fix off-by-one error that led to otherwise-harmless warnings about “apparent wraparound” in subtrans/multixact truncation (Thomas Munro)

- Fix misreporting of `CONTINUE` and `MOVE` statement types in PL/pgSQL's error context messages (Pavel Stehule, Tom Lane)
- Fix PL/Perl to handle non-ASCII error message texts correctly (Alex Hunsaker)
- Fix PL/Python crash when returning the string representation of a `record` result (Tom Lane)
- Fix some places in PL/Tcl that neglected to check for failure of `malloc()` calls (Michael Paquier, Álvaro Herrera)
- In `contrib/isn`, fix output of ISBN-13 numbers that begin with 979 (Fabien Coelho)

EANs beginning with 979 (but not 9790) are considered ISBNs, but they must be printed in the new 13-digit format, not the 10-digit format.

- Fix `contrib/sepysql`'s handling of `SELECT INTO` statements (Kohei KaiGai)
- Improve `libpq`'s handling of out-of-memory conditions (Michael Paquier, Heikki Linnakangas)
- Fix memory leaks and missing out-of-memory checks in `ecpg` (Michael Paquier)
- Fix `psql`'s code for locale-aware formatting of numeric output (Tom Lane)

The formatting code invoked by `\pset numericlocale on` did the wrong thing for some uncommon cases such as numbers with an exponent but no decimal point. It could also mangle already-localized output from the `money` data type.

- Prevent crash in `psql`'s `\c` command when there is no current connection (Noah Misch)
- Make `pg_dump` handle inherited `NOT VALID` check constraints correctly (Tom Lane)
- Fix selection of default `zlib` compression level in `pg_dump`'s directory output format (Andrew Dunstan)
- Ensure that temporary files created during a `pg_dump` run with `tar`-format output are not world-readable (Michael Paquier)
- Fix `pg_dump` and `pg_upgrade` to support cases where the `postgres` or `template1` database is in a non-default tablespace (Marti Raudsepp, Bruce Momjian)
- Fix `pg_dump` to handle object privileges sanely when dumping from a server too old to have a particular privilege type (Tom Lane)

When dumping data types from pre-9.2 servers, and when dumping functions or procedural languages from pre-7.3 servers, `pg_dump` would produce `GRANT/REVOKE` commands that revoked the owner's grantable privileges and instead granted all privileges to `PUBLIC`. Since the privileges involved are just `USAGE` and `EXECUTE`, this isn't a security problem, but it's certainly a surprising representation of the older systems' behavior. Fix it to leave the default privilege state alone in these cases.

- Fix `pg_dump` to dump shell types (Tom Lane)

Shell types (that is, not-yet-fully-defined types) aren't useful for much, but nonetheless `pg_dump` should dump them.

- Fix assorted minor memory leaks in `pg_dump` and other client-side programs (Michael Paquier)
- Fix spinlock assembly code for PPC hardware to be compatible with AIX's native assembler (Tom Lane)

Building with `gcc` didn't work if `gcc` had been configured to use the native assembler, which is becoming more common.

- On AIX, test the `-qlonglong` compiler option rather than just assuming it's safe to use (Noah Misch)
- On AIX, use `-Wl,-brtl1lib` link option to allow symbols to be resolved at runtime (Noah Misch)

Perl relies on this ability in 5.8.0 and later.

- Avoid use of inline functions when compiling with 32-bit xlc, due to compiler bugs (Noah Misch)
- Use `librt` for `sched_yield()` when necessary, which it is on some Solaris versions (Oskari Saaremaa)
- Fix Windows `install.bat` script to handle target directory names that contain spaces (Heikki Linakangas)
- Make the numeric form of the PostgreSQL version number (e.g., 90405) readily available to extension Makefiles, as a variable named `VERSION_NUM` (Michael Paquier)
- Update time zone data files to tzdata release 2015g for DST law changes in Cayman Islands, Fiji, Moldova, Morocco, Norfolk Island, North Korea, Turkey, and Uruguay. There is a new zone name `America/Fort_Nelson` for the Canadian Northern Rockies.

## E.93. Release 9.2.13

**Release date:** 2015-06-12

This release contains a small number of fixes from 9.2.12. For information about new features in the 9.2 major release, see Section E.106.

### E.93.1. Migration to Version 9.2.13

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

### E.93.2. Changes

- Fix rare failure to invalidate relation cache init file (Tom Lane)

With just the wrong timing of concurrent activity, a `VACUUM FULL` on a system catalog might fail to update the “init file” that’s used to avoid cache-loading work for new sessions. This would result in later sessions being unable to access that catalog at all. This is a very ancient bug, but it’s so hard to trigger that no reproducible case had been seen until recently.

- Avoid deadlock between incoming sessions and `CREATE/DROP DATABASE` (Tom Lane)

A new session starting in a database that is the target of a `DROP DATABASE` command, or is the template for a `CREATE DATABASE` command, could cause the command to wait for five seconds and then fail, even if the new session would have exited before that.

## E.94. Release 9.2.12

**Release date:** 2015-06-04

This release contains a small number of fixes from 9.2.11. For information about new features in the 9.2 major release, see Section E.106.

### E.94.1. Migration to Version 9.2.12

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.11, see Section E.95.

### E.94.2. Changes

- Avoid failures while `fsync`'ing data directory during crash restart (Abhijit Menon-Sen, Tom Lane)

In the previous minor releases we added a patch to `fsync` everything in the data directory after a crash. Unfortunately its response to any error condition was to fail, thereby preventing the server

from starting up, even when the problem was quite harmless. An example is that an unwritable file in the data directory would prevent restart on some platforms; but it is common to make SSL certificate files unwritable by the server. Revise this behavior so that permissions failures are ignored altogether, and other types of failures are logged but do not prevent continuing.

- Fix `pg_get_functiondef()` to show functions' `LEAKPROOF` property, if set (Jeevan Chalke)
- Remove `configure`'s check prohibiting linking to a threaded `libpython` on OpenBSD (Tom Lane)

The failure this restriction was meant to prevent seems to not be a problem anymore on current OpenBSD versions.

- Allow `libpq` to use TLS protocol versions beyond v1 (Noah Misch)

For a long time, `libpq` was coded so that the only SSL protocol it would allow was TLS v1. Now that newer TLS versions are becoming popular, allow it to negotiate the highest commonly-supported TLS version with the server. (PostgreSQL servers were already capable of such negotiation, so no change is needed on the server side.) This is a back-patch of a change already released in 9.4.0.

## E.95. Release 9.2.11

**Release date:** 2015-05-22

This release contains a variety of fixes from 9.2.10. For information about new features in the 9.2 major release, see Section E.106.

### E.95.1. Migration to Version 9.2.11

A dump/restore is not required for those running 9.2.X.

However, if you use `contrib/citext`'s `regexp_matches()` functions, see the changelog entry below about that.

Also, if you are upgrading from a version earlier than 9.2.10, see Section E.96.

### E.95.2. Changes

- Avoid possible crash when client disconnects just before the authentication timeout expires (Benkocs Norbert Attila)

If the timeout interrupt fired partway through the session shutdown sequence, SSL-related state would be freed twice, typically causing a crash and hence denial of service to other sessions. Experimentation shows that an unauthenticated remote attacker could trigger the bug somewhat consistently, hence treat as security issue. (CVE-2015-3165)

- Improve detection of system-call failures (Noah Misch)

Our replacement implementation of `snprintf()` failed to check for errors reported by the underlying system library calls; the main case that might be missed is out-of-memory situations. In the worst case this might lead to information exposure, due to our code assuming that a buffer had been overwritten when it hadn't been. Also, there were a few places in which security-relevant calls of other system library functions did not check for failure.

It remains possible that some calls of the `*printf()` family of functions are vulnerable to information disclosure if an out-of-memory error occurs at just the wrong time. We judge the risk to not be large, but will continue analysis in this area. (CVE-2015-3166)

- In `contrib/pgcrypto`, uniformly report decryption failures as “Wrong key or corrupt data” (Noah Misch)

Previously, some cases of decryption with an incorrect key could report other error message texts. It has been shown that such variance in error reports can aid attackers in recovering keys from oth-

er systems. While it's unknown whether `pgcrypto`'s specific behaviors are likewise exploitable, it seems better to avoid the risk by using a one-size-fits-all message. (CVE-2015-3167)

- Fix incorrect declaration of `contrib/citext`'s `regexp_matches()` functions (Tom Lane)

These functions should return `setof text[]`, like the core functions they are wrappers for; but they were incorrectly declared as returning just `text[]`. This mistake had two results: first, if there was no match you got a scalar null result, whereas what you should get is an empty set (zero rows). Second, the `g` flag was effectively ignored, since you would get only one result array even if there were multiple matches.

While the latter behavior is clearly a bug, there might be applications depending on the former behavior; therefore the function declarations will not be changed by default until PostgreSQL 9.5. In pre-9.5 branches, the old behavior exists in version 1.0 of the `citext` extension, while we have provided corrected declarations in version 1.1 (which is *not* installed by default). To adopt the fix in pre-9.5 branches, execute `ALTER EXTENSION citext UPDATE TO '1.1'` in each database in which `citext` is installed. (You can also “update” back to 1.0 if you need to undo that.) Be aware that either update direction will require dropping and recreating any views or rules that use `citext`'s `regexp_matches()` functions.

- Fix incorrect checking of deferred exclusion constraints after a HOT update (Tom Lane)

If a new row that potentially violates a deferred exclusion constraint is HOT-updated (that is, no indexed columns change and the row can be stored back onto the same table page) later in the same transaction, the exclusion constraint would be reported as violated when the check finally occurred, even if the row(s) the new row originally conflicted with had been deleted.

- Fix planning of star-schema-style queries (Tom Lane)

Sometimes, efficient scanning of a large table requires that index parameters be provided from more than one other table (commonly, dimension tables whose keys are needed to index a large fact table). The planner should be able to find such plans, but an overly restrictive search heuristic prevented it.

- Prevent improper reordering of antijoins (NOT EXISTS joins) versus other outer joins (Tom Lane)

This oversight in the planner has been observed to cause “could not find RelOptInfo for given relids” errors, but it seems possible that sometimes an incorrect query plan might get past that consistency check and result in silently-wrong query output.

- Fix incorrect matching of subexpressions in outer-join plan nodes (Tom Lane)

Previously, if textually identical non-strict subexpressions were used both above and below an outer join, the planner might try to re-use the value computed below the join, which would be incorrect because the executor would force the value to NULL in case of an unmatched outer row.

- Fix GEQO planner to cope with failure of its join order heuristic (Tom Lane)

This oversight has been seen to lead to “failed to join all relations together” errors in queries involving `LATERAL`, and that might happen in other cases as well.

- Fix possible deadlock at startup when `max_prepared_transactions` is too small (Heikki Linnakangas)
- Don't archive useless preallocated WAL files after a timeline switch (Heikki Linnakangas)
- Avoid “cannot GetMultiXactIdMembers() during recovery” error (Álvaro Herrera)
- Recursively `fsync()` the data directory after a crash (Abhijit Menon-Sen, Robert Haas)

This ensures consistency if another crash occurs shortly later. (The second crash would have to be a system-level crash, not just a database crash, for there to be a problem.)

- Fix autovacuum launcher's possible failure to shut down, if an error occurs after it receives `SIGTERM` (Álvaro Herrera)

- Cope with unexpected signals in `LockBufferForCleanup()` (Andres Freund)

This oversight could result in spurious errors about “multiple backends attempting to wait for pin-count 1”.

- Fix crash when doing `COPY IN` to a table with check constraints that contain whole-row references (Tom Lane)

The known failure case only crashes in 9.4 and up, but there is very similar code in 9.3 and 9.2, so back-patch those branches as well.

- Avoid waiting for WAL flush or synchronous replication during commit of a transaction that was read-only so far as the user is concerned (Andres Freund)

Previously, a delay could occur at commit in transactions that had written WAL due to HOT page pruning, leading to undesirable effects such as sessions getting stuck at startup if all synchronous replicas are down. Sessions have also been observed to get stuck in catchup interrupt processing when using synchronous replication; this will fix that problem as well.

- Fix crash when manipulating hash indexes on temporary tables (Heikki Linnakangas)
- Fix possible failure during hash index bucket split, if other processes are modifying the index concurrently (Tom Lane)
- Check for interrupts while analyzing index expressions (Jeff Janes)

`ANALYZE` executes index expressions many times; if there are slow functions in such an expression, it's desirable to be able to cancel the `ANALYZE` before that loop finishes.

- Ensure `tableoid` of a foreign table is reported correctly when a `READ COMMITTED` recheck occurs after locking rows in `SELECT FOR UPDATE`, `UPDATE`, or `DELETE` (Etsuro Fujita)
- Add the name of the target server to object description strings for foreign-server user mappings (Alvaro Herrera)
- Recommend setting `include_realm` to 1 when using Kerberos/GSSAPI/SSPI authentication (Stephen Frost)

Without this, identically-named users from different realms cannot be distinguished. For the moment this is only a documentation change, but it will become the default setting in PostgreSQL 9.5.

- Remove code for matching IPv4 `pg_hba.conf` entries to IPv4-in-IPv6 addresses (Tom Lane)

This hack was added in 2003 in response to a report that some Linux kernels of the time would report IPv4 connections as having IPv4-in-IPv6 addresses. However, the logic was accidentally broken in 9.0. The lack of any field complaints since then shows that it's not needed anymore. Now we have reports that the broken code causes crashes on some systems, so let's just remove it rather than fix it. (Had we chosen to fix it, that would make for a subtle and potentially security-sensitive change in the effective meaning of IPv4 `pg_hba.conf` entries, which does not seem like a good thing to do in minor releases.)

- Report WAL flush, not insert, position in `IDENTIFY_SYSTEM` replication command (Heikki Linnakangas)

This avoids a possible startup failure in `pg_receivexlog`.

- While shutting down service on Windows, periodically send status updates to the Service Control Manager to prevent it from killing the service too soon; and ensure that `pg_ctl` will wait for shutdown (Krystian Bigaj)
- Reduce risk of network deadlock when using libpq's non-blocking mode (Heikki Linnakangas)

When sending large volumes of data, it's important to drain the input buffer every so often, in case the server has sent enough response data to cause it to block on output. (A typical scenario is that the server is sending a stream of `NOTICE` messages during `COPY FROM STDIN`.) This worked proper-

ly in the normal blocking mode, but not so much in non-blocking mode. We've modified `libpq` to opportunistically drain input when it can, but a full defense against this problem requires application cooperation: the application should watch for socket read-ready as well as write-ready conditions, and be sure to call `PQconsumeInput()` upon read-ready.

- In `libpq`, fix misparsing of empty values in URI connection strings (Thomas Fanghaenel)
- Fix array handling in `ecpg` (Michael Meskes)
- Fix `psql` to sanely handle URIs and conninfo strings as the first parameter to `\connect` (David Fetter, Andrew Dunstan, Álvaro Herrera)

This syntax has been accepted (but undocumented) for a long time, but previously some parameters might be taken from the old connection instead of the given string, which was agreed to be undesirable.

- Suppress incorrect complaints from `psql` on some platforms that it failed to write `~/.psql_history` at exit (Tom Lane)

This misbehavior was caused by a workaround for a bug in very old (pre-2006) versions of `libedit`. We fixed it by removing the workaround, which will cause a similar failure to appear for anyone still using such versions of `libedit`. Recommendation: upgrade that library, or use `libreadline`.

- Fix `pg_dump`'s rule for deciding which casts are system-provided casts that should not be dumped (Tom Lane)
- In `pg_dump`, fix failure to honor `-z` compression level option together with `-Fd` (Michael Paquier)
- Make `pg_dump` consider foreign key relationships between extension configuration tables while choosing dump order (Gilles Darold, Michael Paquier, Stephen Frost)

This oversight could result in producing dumps that fail to reload because foreign key constraints are transiently violated.

- Fix dumping of views that are just `VALUES (...)` but have column aliases (Tom Lane)
- In `pg_upgrade`, force timeline 1 in the new cluster (Bruce Momjian)

This change prevents upgrade failures caused by bogus complaints about missing WAL history files.

- In `pg_upgrade`, check for improperly non-connectable databases before proceeding (Bruce Momjian)
- In `pg_upgrade`, quote directory paths properly in the generated `delete_old_cluster` script (Bruce Momjian)
- In `pg_upgrade`, preserve database-level freezing info properly (Bruce Momjian)

This oversight could cause missing-clog-file errors for tables within the `postgres` and `template1` databases.

- Run `pg_upgrade` and `pg_resetxlog` with restricted privileges on Windows, so that they don't fail when run by an administrator (Muhammad Asif Naeem)
- Improve handling of `readdir()` failures when scanning directories in `initdb` and `pg_basebackup` (Marco Nenciarini)
- Fix failure in `pg_receivexlog` (Andres Freund)

A patch merge mistake in 9.2.10 led to “could not create archive status file” errors.

- Fix slow sorting algorithm in `contrib/intarray` (Tom Lane)
- Fix compile failure on Sparc V8 machines (Rob Rowan)
- Update time zone data files to `tzdata` release 2015d for DST law changes in Egypt, Mongolia, and Palestine, plus historical changes in Canada and Chile. Also adopt revised zone abbreviations for the America/Adak zone (HST/HDT not HAST/HADT).

## E.96. Release 9.2.10

**Release date:** 2015-02-05

This release contains a variety of fixes from 9.2.9. For information about new features in the 9.2 major release, see Section E.106.

### E.96.1. Migration to Version 9.2.10

A dump/restore is not required for those running 9.2.X.

However, if you are a Windows user and are using the “Norwegian (Bokmål)” locale, manual action is needed after the upgrade to replace any “Norwegian (Bokmål)\_Norway” locale names stored in PostgreSQL system catalogs with the plain-ASCII alias “Norwegian\_Norway”. For details see [http://wiki.postgresql.org/wiki/Changes\\_To\\_Norwegian\\_Locale](http://wiki.postgresql.org/wiki/Changes_To_Norwegian_Locale)

Also, if you are upgrading from a version earlier than 9.2.9, see Section E.97.

### E.96.2. Changes

- Fix buffer overruns in `to_char()` (Bruce Momjian)

When `to_char()` processes a numeric formatting template calling for a large number of digits, PostgreSQL would read past the end of a buffer. When processing a crafted timestamp formatting template, PostgreSQL would write past the end of a buffer. Either case could crash the server. We have not ruled out the possibility of attacks that lead to privilege escalation, though they seem unlikely. (CVE-2015-0241)

- Fix buffer overrun in replacement `*printf()` functions (Tom Lane)

PostgreSQL includes a replacement implementation of `printf` and related functions. This code will overrun a stack buffer when formatting a floating point number (conversion specifiers `e`, `E`, `f`, `F`, `g` or `G`) with requested precision greater than about 500. This will crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. A database user can trigger such a buffer overrun through the `to_char()` SQL function. While that is the only affected core PostgreSQL functionality, extension modules that use `printf`-family functions may be at risk as well.

This issue primarily affects PostgreSQL on Windows. PostgreSQL uses the system implementation of these functions where adequate, which it is on other modern platforms. (CVE-2015-0242)

- Fix buffer overruns in `contrib/pgcrypto` (Marko Tiikkaja, Noah Misch)

Errors in memory size tracking within the `pgcrypto` module permitted stack buffer overruns and improper dependence on the contents of uninitialized memory. The buffer overrun cases can crash the server, and we have not ruled out the possibility of attacks that lead to privilege escalation. (CVE-2015-0243)

- Fix possible loss of frontend/backend protocol synchronization after an error (Heikki Linnakangas)

If any error occurred while the server was in the middle of reading a protocol message from the client, it could lose synchronization and incorrectly try to interpret part of the message's data as a new protocol message. An attacker able to submit crafted binary data within a command parameter might succeed in injecting his own SQL commands this way. Statement timeout and query cancellation are the most likely sources of errors triggering this scenario. Particularly vulnerable are applications that use a timeout and also submit arbitrary user-crafted data as binary query parameters. Disabling statement timeout will reduce, but not eliminate, the risk of exploit. Our thanks to Emil Lenngren for reporting this issue. (CVE-2015-0244)

- Fix information leak via constraint-violation error messages (Stephen Frost)

Some server error messages show the values of columns that violate a constraint, such as a unique constraint. If the user does not have `SELECT` privilege on all columns of the table, this could mean

exposing values that the user should not be able to see. Adjust the code so that values are displayed only when they came from the SQL command or could be selected by the user. (CVE-2014-8161)

- Lock down regression testing's temporary installations on Windows (Noah Misch)

Use SSPI authentication to allow connections only from the OS user who launched the test suite. This closes on Windows the same vulnerability previously closed on other platforms, namely that other users might be able to connect to the test postmaster. (CVE-2014-0067)

- Cope with the Windows locale named "Norwegian (Bokmål)" (Heikki Linnakangas)

Non-ASCII locale names are problematic since it's not clear what encoding they should be represented in. Map the troublesome locale name to a plain-ASCII alias, "Norwegian\_Norway".

- Avoid possible data corruption if `ALTER DATABASE SET TABLESPACE` is used to move a database to a new tablespace and then shortly later move it back to its original tablespace (Tom Lane)
- Avoid corrupting tables when `ANALYZE` inside a transaction is rolled back (Andres Freund, Tom Lane, Michael Paquier)

If the failing transaction had earlier removed the last index, rule, or trigger from the table, the table would be left in a corrupted state with the relevant `pg_class` flags not set though they should be.

- Ensure that unlogged tables are copied correctly during `CREATE DATABASE` or `ALTER DATABASE SET TABLESPACE` (Pavan Deolasee, Andres Freund)
- Fix `DROP`'s dependency searching to correctly handle the case where a table column is recursively visited before its table (Petr Jelinek, Tom Lane)

This case is only known to arise when an extension creates both a datatype and a table using that datatype. The faulty code might refuse a `DROP EXTENSION` unless `CASCADE` is specified, which should not be required.

- Fix use-of-already-freed-memory problem in EvalPlanQual processing (Tom Lane)

In `READ COMMITTED` mode, queries that lock or update recently-updated rows could crash as a result of this bug.

- Fix planning of `SELECT FOR UPDATE` when using a partial index on a child table (Kyotaro Horiguchi)

In `READ COMMITTED` mode, `SELECT FOR UPDATE` must also recheck the partial index's `WHERE` condition when rechecking a recently-updated row to see if it still satisfies the query's `WHERE` condition. This requirement was missed if the index belonged to an inheritance child table, so that it was possible to incorrectly return rows that no longer satisfy the query condition.

- Fix corner case wherein `SELECT FOR UPDATE` could return a row twice, and possibly miss returning other rows (Tom Lane)

In `READ COMMITTED` mode, a `SELECT FOR UPDATE` that is scanning an inheritance tree could incorrectly return a row from a prior child table instead of the one it should return from a later child table.

- Reject duplicate column names in the referenced-columns list of a `FOREIGN KEY` declaration (David Rowley)

This restriction is per SQL standard. Previously we did not reject the case explicitly, but later on the code would fail with bizarre-looking errors.

- Restore previous behavior of conversion of domains to JSON (Tom Lane)

This change causes domains over numeric and boolean to be treated like their base types for purposes of conversion to JSON. It worked like that before 9.3.5 and 9.2.9, but was unintentionally changed while fixing a related problem.

- Fix bugs in raising a numeric value to a large integral power (Tom Lane)

The previous code could get a wrong answer, or consume excessive amounts of time and memory before realizing that the answer must overflow.

- In `numeric_recv()`, truncate away any fractional digits that would be hidden according to the value's `dscale` field (Tom Lane)

A numeric value's display scale (`dscale`) should never be less than the number of nonzero fractional digits; but apparently there's at least one broken client application that transmits binary numeric values in which that's true. This leads to strange behavior since the extra digits are taken into account by arithmetic operations even though they aren't printed. The least risky fix seems to be to truncate away such "hidden" digits on receipt, so that the value is indeed what it prints as.

- Fix incorrect search for shortest-first regular expression matches (Tom Lane)

Matching would often fail when the number of allowed iterations is limited by a `?` quantifier or a bound expression.

- Reject out-of-range numeric timezone specifications (Tom Lane)

Simple numeric timezone specifications exceeding +/- 168 hours (one week) would be accepted, but could then cause null-pointer dereference crashes in certain operations. There's no use-case for such large UTC offsets, so reject them.

- Fix bugs in `tsquery @> tsquery` operator (Heikki Linnakangas)

Two different terms would be considered to match if they had the same CRC. Also, if the second operand had more terms than the first, it would be assumed not to be contained in the first; which is wrong since it might contain duplicate terms.

- Improve `ispell` dictionary's defenses against bad affix files (Tom Lane)
- Allow more than 64K phrases in a thesaurus dictionary (David Boutin)

The previous coding could crash on an oversize dictionary, so this was deemed a back-patchable bug fix rather than a feature addition.

- Fix namespace handling in `xpath()` (Ali Akbar)

Previously, the `xml` value resulting from an `xpath()` call would not have namespace declarations if the namespace declarations were attached to an ancestor element in the input `xml` value, rather than to the specific element being returned. Propagate the ancestral declaration so that the result is correct when considered in isolation.

- Ensure that whole-row variables expose nonempty column names to functions that pay attention to column names within composite arguments (Tom Lane)

In some contexts, constructs like `row_to_json(tab.*)` may not produce the expected column names. This is fixed properly as of 9.4; in older branches, just ensure that we produce some non-empty name. (In some cases this will be the underlying table's column name rather than the query-assigned alias that should theoretically be visible.)

- Fix mishandling of system columns, particularly `tableoid`, in FDW queries (Etsuro Fujita)
- Avoid doing `indexed_column = ANY (array)` as an index qualifier if that leads to an inferior plan (Andrew Gierth)

In some cases, `= ANY` conditions applied to non-first index columns would be done as index conditions even though it would be better to use them as simple filter conditions.

- Fix planner problems with nested append relations, such as inherited tables within `UNION ALL` subqueries (Tom Lane)
- Fail cleanly when a GiST index tuple doesn't fit on a page, rather than going into infinite recursion (Andrew Gierth)

- Exempt tables that have per-table `cost_limit` and/or `cost_delay` settings from autovacuum's global cost balancing rules (Álvaro Herrera)

The previous behavior resulted in basically ignoring these per-table settings, which was unintended. Now, a table having such settings will be vacuumed using those settings, independently of what is going on in other autovacuum workers. This may result in heavier total I/O load than before, so such settings should be re-examined for sanity.

- Avoid wholesale autovacuuming when autovacuum is nominally off (Tom Lane)

Even when autovacuum is nominally off, we will still launch autovacuum worker processes to vacuum tables that are at risk of XID wraparound. However, such a worker process then proceeded to vacuum all tables in the target database, if they met the usual thresholds for autovacuuming. This is at best pretty unexpected; at worst it delays response to the wraparound threat. Fix it so that if autovacuum is turned off, workers *only* do anti-wraparound vacuums and not any other work.

- During crash recovery, ensure that unlogged relations are rewritten as empty and are synced to disk before recovery is considered complete (Abhijit Menon-Sen, Andres Freund)

This prevents scenarios in which unlogged relations might contain garbage data following database crash recovery.

- Fix race condition between hot standby queries and replaying a full-page image (Heikki Linnakangas)

This mistake could result in transient errors in queries being executed in hot standby.

- Fix several cases where recovery logic improperly ignored WAL records for `COMMIT/ABORT PREPARED` (Heikki Linnakangas)

The most notable oversight was that `recovery_target_xid` could not be used to stop at a two-phase commit.

- Prevent latest WAL file from being archived a second time at completion of crash recovery (Fujii Masao)
- Avoid creating unnecessary `.ready` marker files for timeline history files (Fujii Masao)
- Fix possible null pointer dereference when an empty prepared statement is used and the `log_statement` setting is `mod` or `ddl` (Fujii Masao)
- Change “pgstat wait timeout” warning message to be LOG level, and rephrase it to be more understandable (Tom Lane)

This message was originally thought to be essentially a can't-happen case, but it occurs often enough on our slower buildfarm members to be a nuisance. Reduce it to LOG level, and expend a bit more effort on the wording: it now reads “using stale statistics instead of current ones because stats collector is not responding”.

- Fix SPARC spinlock implementation to ensure correctness if the CPU is being run in a non-TSO coherency mode, as some non-Solaris kernels do (Andres Freund)
- Warn if macOS's `setlocale()` starts an unwanted extra thread inside the postmaster (Noah Misch)
- Fix processing of repeated `dbname` parameters in `PQconnectdbParams()` (Alex Shulgin)

Unexpected behavior ensued if the first occurrence of `dbname` contained a connection string or URI to be expanded.

- Ensure that libpq reports a suitable error message on unexpected socket EOF (Marko Tiikkaja, Tom Lane)

Depending on kernel behavior, libpq might return an empty error string rather than something useful when the server unexpectedly closed the socket.

- Clear any old error message during `PQreset()` (Heikki Linnakangas)

If `PQreset()` is called repeatedly, and the connection cannot be re-established, error messages from the failed connection attempts kept accumulating in the `PGconn`'s error string.

- Properly handle out-of-memory conditions while parsing connection options in `libpq` (Alex Shulgin, Heikki Linnakangas)
- Fix array overrun in `ecpg`'s version of `ParseDateTime()` (Michael Paquier)
- In `initdb`, give a clearer error message if a password file is specified but is empty (Mats Erik Andersson)
- Fix `psql`'s `\s` command to work nicely with `libedit`, and add pager support (Stepan Rutz, Tom Lane)

When using `libedit` rather than `readline`, `\s` printed the command history in a fairly unreadable encoded format, and on recent `libedit` versions might fail altogether. Fix that by printing the history ourselves rather than having the library do it. A pleasant side-effect is that the pager is used if appropriate.

This patch also fixes a bug that caused newline encoding to be applied inconsistently when saving the command history with `libedit`. Multiline history entries written by older `psql` versions will be read cleanly with this patch, but perhaps not vice versa, depending on the exact `libedit` versions involved.

- Improve consistency of parsing of `psql`'s special variables (Tom Lane)

Allow variant spellings of `on` and `off` (such as `1/0`) for `ECHO_HIDDEN` and `ON_ERROR_ROLLBACK`. Report a warning for unrecognized values for `COMP_KEYWORD_CASE`, `ECHO`, `ECHO_HIDDEN`, `HISTCONTROL`, `ON_ERROR_ROLLBACK`, and `VERBOSITY`. Recognize all values for all these variables case-insensitively; previously there was a mishmash of case-sensitive and case-insensitive behaviors.

- Fix `psql`'s expanded-mode display to work consistently when using `border = 3` and `linestyle = ascii` or `unicode` (Stephen Frost)
- Improve performance of `pg_dump` when the database contains many instances of multiple dependency paths between the same two objects (Tom Lane)
- Fix `pg_dumpall` to restore its ability to dump from pre-8.1 servers (Gilles Darold)
- Fix possible deadlock during parallel restore of a schema-only dump (Robert Haas, Tom Lane)
- Fix core dump in `pg_dump --binary-upgrade on zero-column composite type` (Rushabh Lathia)
- Prevent WAL files created by `pg_basebackup -x/-X` from being archived again when the standby is promoted (Andres Freund)
- Fix failure of `contrib/auto_explain` to print per-node timing information when doing `EXPLAIN ANALYZE` (Tom Lane)
- Fix upgrade-from-unpackaged script for `contrib/citext` (Tom Lane)
- Fix block number checking in `contrib/pageinspect`'s `get_raw_page()` (Tom Lane)

The incorrect checking logic could prevent access to some pages in non-main relation forks.

- Fix `contrib/pgcrypto`'s `pgp_sym_decrypt()` to not fail on messages whose length is 6 less than a power of 2 (Marko Tiikkaja)
- Fix file descriptor leak in `contrib/pg_test_fsync` (Jeff Janes)

This could cause failure to remove temporary files on Windows.

- Handle unexpected query results, especially NULLs, safely in `contrib/tablefunc`'s `connectby()` (Michael Paquier)

`connectby()` previously crashed if it encountered a NULL key value. It now prints that row but doesn't recurse further.

- Avoid a possible crash in `contrib/xml2's xslt_process()` (Mark Simonetti)

`libxslt` seems to have an undocumented dependency on the order in which resources are freed; re-order our calls to avoid a crash.

- Mark some `contrib` I/O functions with correct volatility properties (Tom Lane)

The previous over-conservative marking was immaterial in normal use, but could cause optimization problems or rejection of valid index expression definitions. Since the consequences are not large, we've just adjusted the function definitions in the extension modules' scripts, without changing version numbers.

- Numerous cleanups of warnings from Coverity static code analyzer (Andres Freund, Tatsuo Ishii, Marko Kreen, Tom Lane, Michael Paquier)

These changes are mostly cosmetic but in some cases fix corner-case bugs, for example a crash rather than a proper error report after an out-of-memory failure. None are believed to represent security issues.

- Detect incompatible OpenLDAP versions during build (Noah Misch)

With OpenLDAP versions 2.4.24 through 2.4.31, inclusive, PostgreSQL backends can crash at exit. Raise a warning during configure based on the compile-time OpenLDAP version number, and test the crashing scenario in the `contrib/dblink` regression test.

- In non-MSVC Windows builds, ensure `libpq.dll` is installed with execute permissions (Noah Misch)
- Make `pg_regress` remove any temporary installation it created upon successful exit (Tom Lane)

This results in a very substantial reduction in disk space usage during `make check-world`, since that sequence involves creation of numerous temporary installations.

- Support time zone abbreviations that change UTC offset from time to time (Tom Lane)

Previously, PostgreSQL assumed that the UTC offset associated with a time zone abbreviation (such as `EST`) never changes in the usage of any particular locale. However this assumption fails in the real world, so introduce the ability for a zone abbreviation to represent a UTC offset that sometimes changes. Update the zone abbreviation definition files to make use of this feature in timezone locales that have changed the UTC offset of their abbreviations since 1970 (according to the IANA timezone database). In such timezones, PostgreSQL will now associate the correct UTC offset with the abbreviation depending on the given date.

- Update time zone abbreviations lists (Tom Lane)

Add `CST` (China Standard Time) to our lists. Remove references to `ADT` as “Arabia Daylight Time”, an abbreviation that's been out of use since 2007; therefore, claiming there is a conflict with “Atlantic Daylight Time” doesn't seem especially helpful. Fix entirely incorrect GMT offsets for `CKT` (Cook Islands), `FJT`, and `FJST` (Fiji); we didn't even have them on the proper side of the date line.

- Update time zone data files to tzdata release 2015a.

The IANA timezone database has adopted abbreviations of the form `AxST/AxDT` for all Australian time zones, reflecting what they believe to be current majority practice Down Under. These names do not conflict with usage elsewhere (other than `ACST` for Acre Summer Time, which has been in disuse since 1994). Accordingly, adopt these names into our “Default” timezone abbreviation set. The “Australia” abbreviation set now contains only `CST`, `EAST`, `EST`, `SAST`, `SAT`, and `WST`, all of which are thought to be mostly historical usage. Note that `SAST` has also been changed to be South Africa Standard Time in the “Default” abbreviation set.

Also, add zone abbreviations `SRET` (Asia/Srednekolymsk) and `XJT` (Asia/Urumqi), and use `WSST/WSDT` for western Samoa. Also, there were DST law changes in Chile, Mexico, the Turks & Caicos Islands (America/Grand\_Turk), and Fiji. There is a new zone Pacific/Bougainville for portions of Papua New Guinea. Also, numerous corrections for historical (pre-1970) time zone data.

## E.97. Release 9.2.9

**Release date:** 2014-07-24

This release contains a variety of fixes from 9.2.8. For information about new features in the 9.2 major release, see Section E.106.

### E.97.1. Migration to Version 9.2.9

A dump/restore is not required for those running 9.2.X.

However, this release corrects an index corruption problem in some GiST indexes. See the first changelog entry below to find out whether your installation has been affected and what steps you should take if so.

Also, if you are upgrading from a version earlier than 9.2.6, see Section E.100.

### E.97.2. Changes

- Correctly initialize padding bytes in `contrib/btree_gist` indexes on `bit` columns (Heikki Linnakangas)

This error could result in incorrect query results due to values that should compare equal not being seen as equal. Users with GiST indexes on `bit` or `bit varying` columns should `REINDEX` those indexes after installing this update.

- Protect against torn pages when deleting GIN list pages (Heikki Linnakangas)

This fix prevents possible index corruption if a system crash occurs while the page update is being written to disk.

- Don't clear the right-link of a GiST index page while replaying updates from WAL (Heikki Linnakangas)

This error could lead to transiently wrong answers from GiST index scans performed in Hot Standby.

- Fix corner-case infinite loop during insertion into an SP-GiST text index (Tom Lane)
- Fix feedback status when `hot_standby_feedback` is turned off on-the-fly (Simon Riggs)
- Fix possibly-incorrect cache invalidation during nested calls to `ReceiveSharedInvalidMessages` (Andres Freund)
- Fix planner's mishandling of nested `PlaceholderVars` generated in nested-`nestloop` plans (Tom Lane)

This oversight could result in “variable not found in subplan target lists” errors, or in silently wrong query results.

- Fix “could not find pathkey item to sort” planner failures with `UNION ALL` over subqueries reading from tables with inheritance children (Tom Lane)
- Don't assume a subquery's output is unique if there's a set-returning function in its targetlist (David Rowley)

This oversight could lead to misoptimization of constructs like `WHERE x IN (SELECT y, generate_series(1,10) FROM t GROUP BY y)`.

- Improve planner to drop constant-NULL inputs of `AND/OR` when possible (Tom Lane)

This change fixes some cases where the more aggressive parameter substitution done by 9.2 and later can lead to a worse plan than older versions produced.

- Fix identification of input type category in `to_json()` and friends (Tom Lane)

This is known to have led to inadequate quoting of `money` fields in the `JSON` result, and there may have been wrong results for other data types as well.

- Fix failure to de-toast fields in composite elements of structured types (Tom Lane)

This corrects cases where `TOAST` pointers could be copied into other tables without being dereferenced. If the original data is later deleted, it would lead to errors like “missing chunk number 0 for toast value ...” when the now-dangling pointer is used.

- Fix “record type has not been registered” failures with whole-row references to the output of `Append plan nodes` (Tom Lane)
- Fix possible crash when invoking a user-defined function while rewinding a cursor (Tom Lane)
- Fix query-lifespan memory leak while evaluating the arguments for a function in `FROM` (Tom Lane)
- Fix session-lifespan memory leaks in regular-expression processing (Tom Lane, Arthur O'Dwyer, Greg Stark)
- Fix data encoding error in `hungarian.stop` (Tom Lane)
- Prevent foreign tables from being created with `OIDS` when `default_with_oids` is true (Etsuro Fujita)
- Fix liveness checks for rows that were inserted in the current transaction and then deleted by a now-rolled-back subtransaction (Andres Freund)

This could cause problems (at least spurious warnings, and at worst an infinite loop) if `CREATE INDEX` or `CLUSTER` were done later in the same transaction.

- Clear `pg_stat_activity.xact_start` during `PREPARE TRANSACTION` (Andres Freund)

After the `PREPARE`, the originating session is no longer in a transaction, so it should not continue to display a transaction start time.

- Fix `REASSIGN OWNED` to not fail for text search objects (Álvaro Herrera)
- Block signals during postmaster startup (Tom Lane)

This ensures that the postmaster will properly clean up after itself if, for example, it receives `SIGINT` while still starting up.

- Fix client host name lookup when processing `pg_hba.conf` entries that specify host names instead of IP addresses (Tom Lane)

Ensure that reverse-DNS lookup failures are reported, instead of just silently not matching such entries. Also ensure that we make only one reverse-DNS lookup attempt per connection, not one per host name entry, which is what previously happened if the lookup attempts failed.

- Allow the root user to use `postgres -C variable` and `postgres --describe-config` (MauMau)

The prohibition on starting the server as root does not need to extend to these operations, and relaxing it prevents failure of `pg_ctl` in some scenarios.

- Secure Unix-domain sockets of temporary postmasters started during `make check` (Noah Misch)

Any local user able to access the socket file could connect as the server's bootstrap superuser, then proceed to execute arbitrary code as the operating-system user running the test, as we previously noted in `CVE-2014-0067`. This change defends against that risk by placing the server's socket in a temporary, mode `0700` subdirectory of `/tmp`. The hazard remains however on platforms where Unix sockets are not supported, notably Windows, because then the temporary postmaster must accept local TCP connections.

A useful side effect of this change is to simplify `make check` testing in builds that override `DEFAULT_PGSOCKET_DIR`. Popular non-default values like `/var/run/postgresql` are often not writable by the build user, requiring workarounds that will no longer be necessary.

- Fix tablespace creation WAL replay to work on Windows (MauMau)

- Fix detection of socket creation failures on Windows (Bruce Momjian)
- On Windows, allow new sessions to absorb values of PGC\_BACKEND parameters (such as log\_connections) from the configuration file (Amit Kapila)

Previously, if such a parameter were changed in the file post-startup, the change would have no effect.

- Properly quote executable path names on Windows (Nikhil Deshpande)

This oversight could cause `initdb` and `pg_upgrade` to fail on Windows, if the installation path contained both spaces and `@` signs.

- Fix linking of `libpython` on macOS (Tom Lane)

The method we previously used can fail with the Python library supplied by Xcode 5.0 and later.

- Avoid buffer bloat in `libpq` when the server consistently sends data faster than the client can absorb it (Shin-ichi Morita, Tom Lane)

`libpq` could be coerced into enlarging its input buffer until it runs out of memory (which would be reported misleadingly as “lost synchronization with server”). Under ordinary circumstances it's quite far-fetched that data could be continuously transmitted more quickly than the `recv()` loop can absorb it, but this has been observed when the client is artificially slowed by scheduler constraints.

- Ensure that LDAP lookup attempts in `libpq` time out as intended (Laurenz Albe)
- Fix `ecpg` to do the right thing when an array of `char *` is the target for a `FETCH` statement returning more than one row, as well as some other array-handling fixes (Ashutosh Bapat)
- Fix `pg_restore`'s processing of old-style large object comments (Tom Lane)

A direct-to-database restore from an archive file generated by a pre-9.0 version of `pg_dump` would usually fail if the archive contained more than a few comments for large objects.

- Fix `pg_upgrade` for cases where the new server creates a `TOAST` table but the old version did not (Bruce Momjian)

This rare situation would manifest as “relation OID mismatch” errors.

- Prevent `contrib/auto_explain` from changing the output of a user's `EXPLAIN` (Tom Lane)

If `auto_explain` is active, it could cause an `EXPLAIN (ANALYZE, TIMING OFF)` command to nonetheless print timing information.

- Fix query-lifespan memory leak in `contrib/dblink` (MauMau, Joe Conway)
- In `contrib/pgcrypto` functions, ensure sensitive information is cleared from stack variables before returning (Marko Kreen)
- Prevent use of already-freed memory in `contrib/pgstattuple`'s `pgstat_heap()` (Noah Misch)
- In `contrib/uuid-ossdp`, cache the state of the OSSDP UUID library across calls (Tom Lane)

This improves the efficiency of UUID generation and reduces the amount of entropy drawn from `/dev/urandom`, on platforms that have that.

- Update time zone data files to `tzdata` release 2014e for DST law changes in Crimea, Egypt, and Morocco.

## E.98. Release 9.2.8

**Release date:** 2014-03-20

This release contains a variety of fixes from 9.2.7. For information about new features in the 9.2 major release, see Section E.106.

## E.98.1. Migration to Version 9.2.8

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.6, see Section E.100.

## E.98.2. Changes

- Restore GIN metapages unconditionally to avoid torn-page risk (Heikki Linnakangas)

Although this oversight could theoretically result in a corrupted index, it is unlikely to have caused any problems in practice, since the active part of a GIN metapage is smaller than a standard 512-byte disk sector.

- Avoid race condition in checking transaction commit status during receipt of a `NOTIFY` message (Marko Tiikkaja)

This prevents a scenario wherein a sufficiently fast client might respond to a notification before database updates made by the notifier have become visible to the recipient.

- Allow regular-expression operators to be terminated early by query cancel requests (Tom Lane)

This prevents scenarios wherein a pathological regular expression could lock up a server process uninterruptibly for a long time.

- Remove incorrect code that tried to allow `OVERLAPS` with single-element row arguments (Joshua Yanovski)

This code never worked correctly, and since the case is neither specified by the SQL standard nor documented, it seemed better to remove it than fix it.

- Avoid getting more than `AccessShareLock` when de-parsing a rule or view (Dean Rasheed)

This oversight resulted in `pg_dump` unexpectedly acquiring `RowExclusiveLock` locks on tables mentioned as the targets of `INSERT/UPDATE/DELETE` commands in rules. While usually harmless, that could interfere with concurrent transactions that tried to acquire, for example, `ShareLock` on those tables.

- Improve performance of index endpoint probes during planning (Tom Lane)

This change fixes a significant performance problem that occurred when there were many not-yet-committed rows at the end of the index, which is a common situation for indexes on sequentially-assigned values such as timestamps or sequence-generated identifiers.

- Fix walsender's failure to shut down cleanly when client is `pg_receivexlog` (Fujii Masao)
- Check WAL level and hot standby parameters correctly when doing crash recovery that will be followed by archive recovery (Heikki Linnakangas)
- Fix test to see if hot standby connections can be allowed immediately after a crash (Heikki Linnakangas)
- Prevent interrupts while reporting non-`ERROR` messages (Tom Lane)

This guards against rare server-process freezeups due to recursive entry to `syslog()`, and perhaps other related problems.

- Fix memory leak in PL/Perl when returning a composite result, including multiple-OUT-parameter cases (Alex Hunsaker)
- Fix tracking of `psql` script line numbers during `\copy` from out-of-line data (Kumar Rajeev Rastogi, Amit Khandekar)

`\copy ... from` incremented the script file line number for each data line, even if the data was not coming from the script file. This mistake resulted in wrong line numbers being reported for any errors occurring later in the same script file.

- Prevent intermittent “could not reserve shared memory region” failures on recent Windows versions (MauMau)
- Update time zone data files to tzdata release 2014a for DST law changes in Fiji and Turkey, plus historical changes in Israel and Ukraine.

## E.99. Release 9.2.7

**Release date:** 2014-02-20

This release contains a variety of fixes from 9.2.6. For information about new features in the 9.2 major release, see Section E.106.

### E.99.1. Migration to Version 9.2.7

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.6, see Section E.100.

### E.99.2. Changes

- Shore up `GRANT ... WITH ADMIN OPTION` restrictions (Noah Misch)

Granting a role without `ADMIN OPTION` is supposed to prevent the grantee from adding or removing members from the granted role, but this restriction was easily bypassed by doing `SET ROLE` first. The security impact is mostly that a role member can revoke the access of others, contrary to the wishes of his grantor. Unapproved role member additions are a lesser concern, since an uncooperative role member could provide most of his rights to others anyway by creating views or `SECURITY DEFINER` functions. (CVE-2014-0060)

- Prevent privilege escalation via manual calls to PL validator functions (Andres Freund)

The primary role of PL validator functions is to be called implicitly during `CREATE FUNCTION`, but they are also normal SQL functions that a user can call explicitly. Calling a validator on a function actually written in some other language was not checked for and could be exploited for privilege-escalation purposes. The fix involves adding a call to a privilege-checking function in each validator function. Non-core procedural languages will also need to make this change to their own validator functions, if any. (CVE-2014-0061)

- Avoid multiple name lookups during table and index DDL (Robert Haas, Andres Freund)

If the name lookups come to different conclusions due to concurrent activity, we might perform some parts of the DDL on a different table than other parts. At least in the case of `CREATE INDEX`, this can be used to cause the permissions checks to be performed against a different table than the index creation, allowing for a privilege escalation attack. (CVE-2014-0062)

- Prevent buffer overrun with long datetime strings (Noah Misch)

The `MAXDATELEN` constant was too small for the longest possible value of type `interval`, allowing a buffer overrun in `interval_out()`. Although the datetime input functions were more careful about avoiding buffer overrun, the limit was short enough to cause them to reject some valid inputs, such as input containing a very long timezone name. The `ecpg` library contained these vulnerabilities along with some of its own. (CVE-2014-0063)

- Prevent buffer overrun due to integer overflow in size calculations (Noah Misch, Heikki Linnakangas)

Several functions, mostly type input functions, calculated an allocation size without checking for overflow. If overflow did occur, a too-small buffer would be allocated and then written past. (CVE-2014-0064)

- Prevent overruns of fixed-size buffers (Peter Eisentraut, Jozef Mlich)

Use `strncpy()` and related functions to provide a clear guarantee that fixed-size buffers are not overrun. Unlike the preceding items, it is unclear whether these cases really represent live issues, since in most cases there appear to be previous constraints on the size of the input string. Nonetheless it seems prudent to silence all Coverity warnings of this type. (CVE-2014-0065)

- Avoid crashing if `crypt()` returns NULL (Honza Horak, Bruce Momjian)

There are relatively few scenarios in which `crypt()` could return NULL, but `contrib/chkpass` would crash if it did. One practical case in which this could be an issue is if `libc` is configured to refuse to execute unapproved hashing algorithms (e.g., “FIPS mode”). (CVE-2014-0066)

- Document risks of `make check` in the regression testing instructions (Noah Misch, Tom Lane)

Since the temporary server started by `make check` uses “trust” authentication, another user on the same machine could connect to it as database superuser, and then potentially exploit the privileges of the operating-system user who started the tests. A future release will probably incorporate changes in the testing procedure to prevent this risk, but some public discussion is needed first. So for the moment, just warn people against using `make check` when there are untrusted users on the same machine. (CVE-2014-0067)

- Fix possible mis-replay of WAL records when some segments of a relation aren't full size (Greg Stark, Tom Lane)

The WAL update could be applied to the wrong page, potentially many pages past where it should have been. Aside from corrupting data, this error has been observed to result in significant “bloat” of standby servers compared to their masters, due to updates being applied far beyond where the end-of-file should have been. This failure mode does not appear to be a significant risk during crash recovery, only when initially synchronizing a standby created from a base backup taken from a quickly-changing master.

- Fix bug in determining when recovery has reached consistency (Tomonari Katsumata, Heikki Linnakangas)

In some cases WAL replay would mistakenly conclude that the database was already consistent at the start of replay, thus possibly allowing hot-standby queries before the database was really consistent. Other symptoms such as “PANIC: WAL contains references to invalid pages” were also possible.

- Fix improper locking of btree index pages while replaying a `VACUUM` operation in hot-standby mode (Andres Freund, Heikki Linnakangas, Tom Lane)

This error could result in “PANIC: WAL contains references to invalid pages” failures.

- Ensure that insertions into non-leaf GIN index pages write a full-page WAL record when appropriate (Heikki Linnakangas)

The previous coding risked index corruption in the event of a partial-page write during a system crash.

- When `pause_at_recovery_target` and `recovery_target_inclusive` are both set, ensure the target record is applied before pausing, not after (Heikki Linnakangas)
- Fix race conditions during server process exit (Robert Haas)

Ensure that signal handlers don't attempt to use the process's `MyProc` pointer after it's no longer valid.

- Fix race conditions in walsender shutdown logic and walreceiver SIGHUP signal handler (Tom Lane)
- Fix unsafe references to `errno` within error reporting logic (Christian Kruse)

This would typically lead to odd behaviors such as missing or inappropriate `HINT` fields.

- Fix possible crashes from using `ereport()` too early during server startup (Tom Lane)

The principal case we've seen in the field is a crash if the server is started in a directory it doesn't have permission to read.

- Clear retry flags properly in OpenSSL socket write function (Alexander Kukushkin)

This omission could result in a server lockup after unexpected loss of an SSL-encrypted connection.

- Fix length checking for Unicode identifiers (`U&"..."` syntax) containing escapes (Tom Lane)

A spurious truncation warning would be printed for such identifiers if the escaped form of the identifier was too long, but the identifier actually didn't need truncation after de-escaping.

- Allow keywords that are type names to be used in lists of roles (Stephen Frost)

A previous patch allowed such keywords to be used without quoting in places such as role identifiers; but it missed cases where a list of role identifiers was permitted, such as `DROP ROLE`.

- Fix parser crash for `EXISTS(SELECT * FROM zero_column_table)` (Tom Lane)
- Fix possible crash due to invalid plan for nested sub-selects, such as `WHERE (... x IN (SELECT ...) ...)` IN `(SELECT ...)` (Tom Lane)
- Fix `UPDATE/DELETE` of an inherited target table that has `UNION ALL` subqueries (Tom Lane)

Without this fix, `UNION ALL` subqueries aren't correctly inserted into the update plans for inheritance child tables after the first one, typically resulting in no update happening for those child table(s).

- Ensure that `ANALYZE` creates statistics for a table column even when all the values in it are “too wide” (Tom Lane)

`ANALYZE` intentionally omits very wide values from its histogram and most-common-values calculations, but it neglected to do something sane in the case that all the sampled entries are too wide.

- In `ALTER TABLE ... SET TABLESPACE`, allow the database's default tablespace to be used without a permissions check (Stephen Frost)

`CREATE TABLE` has always allowed such usage, but `ALTER TABLE` didn't get the memo.

- Fix “cannot accept a set” error when some arms of a `CASE` return a set and others don't (Tom Lane)
- Properly distinguish numbers from non-numbers when generating JSON output (Andrew Dunstan)
- Fix checks for all-zero client addresses in `pgstat` functions (Kevin Grittner)
- Fix possible misclassification of multibyte characters by the text search parser (Tom Lane)

Non-ASCII characters could be misclassified when using C locale with a multibyte encoding. On Cygwin, non-C locales could fail as well.

- Fix possible misbehavior in `plainto_tsquery()` (Heikki Linnakangas)

Use `memmove()` not `memcpy()` for copying overlapping memory regions. There have been no field reports of this actually causing trouble, but it's certainly risky.

- Fix placement of permissions checks in `pg_start_backup()` and `pg_stop_backup()` (Andres Freund, Magnus Hagander)

The previous coding might attempt to do catalog access when it shouldn't.

- Accept `SHIFT_JIS` as an encoding name for locale checking purposes (Tatsuo Ishii)
- Fix \*-qualification of named parameters in SQL-language functions (Tom Lane)

Given a composite-type parameter named `foo`, `$1.*` worked fine, but `foo.*` not so much.

- Fix misbehavior of `PQhost()` on Windows (Fujii Masao)

It should return `localhost` if no host has been specified.

- Improve error handling in `libpq` and `psql` for failures during `COPY TO STDOUT/FROM STDIN` (Tom Lane)

In particular this fixes an infinite loop that could occur in 9.2 and up if the server connection was lost during `COPY FROM STDIN`. Variants of that scenario might be possible in older versions, or with other client applications.

- Fix incorrect translation handling in some `psql \d` commands (Peter Eisentraut, Tom Lane)
- Ensure `pg_basebackup`'s background process is killed when exiting its foreground process (Magnus Hagander)
- Fix possible incorrect printing of filenames in `pg_basebackup`'s verbose mode (Magnus Hagander)
- Avoid including tablespaces inside PGDATA twice in base backups (Dimitri Fontaine, Magnus Hagander)
- Fix misaligned descriptors in `ecpg` (MauMau)
- In `ecpg`, handle lack of a hostname in the connection parameters properly (Michael Meskes)
- Fix performance regression in `contrib/dblink` connection startup (Joe Conway)

Avoid an unnecessary round trip when client and server encodings match.

- In `contrib/isn`, fix incorrect calculation of the check digit for ISMN values (Fabien Coelho)
- Fix `contrib/pg_stat_statement`'s handling of `CURRENT_DATE` and related constructs (Kyotaro Horiguchi)
- Ensure client-code-only installation procedure works as documented (Peter Eisentraut)
- In Mingw and Cygwin builds, install the `libpq` DLL in the `bin` directory (Andrew Dunstan)

This duplicates what the MSVC build has long done. It should fix problems with programs like `psql` failing to start because they can't find the DLL.

- Avoid using the deprecated `dllwrap` tool in Cygwin builds (Marco Atzeri)
- Don't generate plain-text `HISTORY` and `src/test/regress/README` files anymore (Tom Lane)

These text files duplicated the main HTML and PDF documentation formats. The trouble involved in maintaining them greatly outweighs the likely audience for plain-text format. Distribution tarballs will still contain files by these names, but they'll just be stubs directing the reader to consult the main documentation. The plain-text `INSTALL` file will still be maintained, as there is arguably a use-case for that.

- Update time zone data files to `tzdata` release 2013i for DST law changes in Jordan and historical changes in Cuba.

In addition, the zones `Asia/Riyadh87`, `Asia/Riyadh88`, and `Asia/Riyadh89` have been removed, as they are no longer maintained by IANA, and never represented actual civil timekeeping practice.

## E.100. Release 9.2.6

**Release date:** 2013-12-05

This release contains a variety of fixes from 9.2.5. For information about new features in the 9.2 major release, see Section E.106.

### E.100.1. Migration to Version 9.2.6

A dump/restore is not required for those running 9.2.X.

However, this release corrects a number of potential data corruption issues. See the first two changelog entries below to find out whether your installation has been affected and what steps you can take if so.

Also, if you are upgrading from a version earlier than 9.2.4, see Section E.102.

## E.100.2. Changes

- Fix `VACUUM`'s tests to see whether it can update `relfrozenxid` (Andres Freund)

In some cases `VACUUM` (either manual or `autovacuum`) could incorrectly advance a table's `relfrozenxid` value, allowing tuples to escape freezing, causing those rows to become invisible once  $2^{31}$  transactions have elapsed. The probability of data loss is fairly low since multiple incorrect advancements would need to happen before actual loss occurs, but it's not zero. In 9.2.0 and later, the probability of loss is higher, and it's also possible to get “could not access status of transaction” errors as a consequence of this bug. Users upgrading from releases 9.0.4 or 8.4.8 or earlier are not affected, but all later versions contain the bug.

The issue can be ameliorated by, after upgrading, vacuuming all tables in all databases while having `vacuum_freeze_table_age` set to zero. This will fix any latent corruption but will not be able to fix all pre-existing data errors. However, an installation can be presumed safe after performing this vacuuming if it has executed fewer than  $2^{31}$  update transactions in its lifetime (check this with `SELECT txid_current() < 2^31`).

- Fix initialization of `pg_clog` and `pg_subtrans` during hot standby startup (Andres Freund, Heikki Linnakangas)

This bug can cause data loss on standby servers at the moment they start to accept hot-standby queries, by marking committed transactions as uncommitted. The likelihood of such corruption is small unless, at the time of standby startup, the primary server has executed many updating transactions since its last checkpoint. Symptoms include missing rows, rows that should have been deleted being still visible, and obsolete versions of updated rows being still visible alongside their newer versions.

This bug was introduced in versions 9.3.0, 9.2.5, 9.1.10, and 9.0.14. Standby servers that have only been running earlier releases are not at risk. It's recommended that standby servers that have ever run any of the buggy releases be re-cloned from the primary (e.g., with a new base backup) after upgrading.

- Fix dangling-pointer problem in fast-path locking (Tom Lane)

This could lead to corruption of the lock data structures in shared memory, causing “lock already held” and other odd errors.

- Truncate `pg_multixact` contents during WAL replay (Andres Freund)

This avoids ever-increasing disk space consumption in standby servers.

- Ensure an anti-wraparound `VACUUM` counts a page as scanned when it's only verified that no tuples need freezing (Sergey Burladyan, Jeff Janes)

This bug could result in failing to advance `relfrozenxid`, so that the table would still be thought to need another anti-wraparound vacuum. In the worst case the database might even shut down to prevent wraparound.

- Fix race condition in GIN index posting tree page deletion (Heikki Linnakangas)

This could lead to transient wrong answers or query failures.

- Fix “unexpected `spgdoinsert()` failure” error during SP-GiST index creation (Teodor Sigaev)
- Avoid flattening a subquery whose `SELECT` list contains a volatile function wrapped inside a `sub-SELECT` (Tom Lane)

This avoids unexpected results due to extra evaluations of the volatile function.

- Fix planner's processing of non-simple-variable subquery outputs nested within outer joins (Tom Lane)

This error could lead to incorrect plans for queries involving multiple levels of subqueries within `JOIN` syntax.

- Fix incorrect planning in cases where the same non-strict expression appears in multiple `WHERE` and outer `JOIN` equality clauses (Tom Lane)
- Fix planner crash with whole-row reference to a subquery (Tom Lane)
- Fix incorrect generation of optimized `MIN()/MAX()` plans for inheritance trees (Tom Lane)

The planner could fail in cases where the `MIN()/MAX()` argument was an expression rather than a simple variable.

- Fix premature deletion of temporary files (Andres Freund)
- Prevent intra-transaction memory leak when printing range values (Tom Lane)

This fix actually cures transient memory leaks in any datatype output function, but range types are the only ones known to have had a significant problem.

- Prevent incorrect display of dropped columns in `NOT NULL` and `CHECK` constraint violation messages (Michael Paquier and Tom Lane)
- Allow default arguments and named-argument notation for window functions (Tom Lane)

Previously, these cases were likely to crash.

- Fix possible read past end of memory in rule printing (Peter Eisentraut)
- Fix array slicing of `int2vector` and `oidvector` values (Tom Lane)

Expressions of this kind are now implicitly promoted to regular `int2` or `oid` arrays.

- Fix incorrect behaviors when using a SQL-standard, simple GMT offset timezone (Tom Lane)

In some cases, the system would use the simple GMT offset value when it should have used the regular timezone setting that had prevailed before the simple offset was selected. This change also causes the `timeofday` function to honor the simple GMT offset zone.

- Prevent possible misbehavior when logging translations of Windows error codes (Tom Lane)
- Properly quote generated command lines in `pg_ctl` (Naoya Anzai and Tom Lane)

This fix applies only to Windows.

- Fix `pg_dumpall` to work when a source database sets `default_transaction_read_only` via `ALTER DATABASE SET` (Kevin Grittner)

Previously, the generated script would fail during restore.

- Make `ecpg` search for quoted cursor names case-sensitively (Zoltán Böszörményi)
- Fix `ecpg`'s processing of lists of variables declared `varchar` (Zoltán Böszörményi)
- Make `contrib/lo` defend against incorrect trigger definitions (Marc Cousin)
- Update time zone data files to `tzdata` release 2013h for DST law changes in Argentina, Brazil, Jordan, Libya, Liechtenstein, Morocco, and Palestine. Also, new timezone abbreviations `WIB`, `WIT`, `WITA` for Indonesia.

## E.101. Release 9.2.5

**Release date:** 2013-10-10

This release contains a variety of fixes from 9.2.4. For information about new features in the 9.2 major release, see Section E.106.

## E.101.1. Migration to Version 9.2.5

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.4, see Section E.102.

## E.101.2. Changes

- Prevent corruption of multi-byte characters when attempting to case-fold identifiers (Andrew Dunstan)

PostgreSQL case-folds non-ASCII characters only when using a single-byte server encoding.

- Fix memory leak when creating B-tree indexes on range columns (Heikki Linnakangas)
- Fix checkpoint memory leak in background writer when `wal_level = hot_standby` (Naoya Anzai)
- Fix memory leak caused by `lo_open()` failure (Heikki Linnakangas)
- Fix memory overcommit bug when `work_mem` is using more than 24GB of memory (Stephen Frost)
- Serializable snapshot fixes (Kevin Grittner, Heikki Linnakangas)
- Fix deadlock bug in libpq when using SSL (Stephen Frost)
- Fix possible SSL state corruption in threaded libpq applications (Nick Phillips, Stephen Frost)
- Improve estimate of planner cost when choosing between generic and custom plans (Tom Lane)

This change will favor generic plans when planning cost is high.

- Properly compute row estimates for boolean columns containing many NULL values (Andrew Gierth)

Previously tests like `col IS NOT TRUE` and `col IS NOT FALSE` did not properly factor in NULL values when estimating plan costs.

- Fix accounting for qualifier evaluation costs in `UNION ALL` and inheritance queries (Tom Lane)

This fixes cases where suboptimal query plans could be chosen if some `WHERE` clauses are expensive to calculate.

- Prevent pushing down `WHERE` clauses into unsafe `UNION/INTERSECT` subqueries (Tom Lane)

Subqueries of a `UNION` or `INTERSECT` that contain set-returning functions or volatile functions in their `SELECT` lists could be improperly optimized, leading to run-time errors or incorrect query results.

- Fix rare case of “failed to locate grouping columns” planner failure (Tom Lane)
- Fix `pg_dump` of foreign tables with dropped columns (Andrew Dunstan)

Previously such cases could cause a `pg_upgrade` error.

- Reorder `pg_dump` processing of extension-related rules and event triggers (Joe Conway)
- Force dumping of extension tables if specified by `pg_dump -t` or `-n` (Joe Conway)
- Improve view dumping code's handling of dropped columns in referenced tables (Tom Lane)
- Fix `pg_restore -l` with the directory archive to display the correct format name (Fujii Masao)
- Properly record index comments created using `UNIQUE` and `PRIMARY KEY` syntax (Andres Freund)

This fixes a parallel `pg_restore` failure.

- Cause `pg_basebackup -x` with an empty xlog directory to throw an error rather than crashing (Magnus Hagander, Haruka Takatsuka)

- Properly guarantee transmission of WAL files before clean switchover (Fujii Masao)

Previously, the streaming replication connection might close before all WAL files had been replayed on the standby.

- Fix WAL segment timeline handling during recovery (Mitsumasa Kondo, Heikki Linnakangas)

WAL file recycling during standby recovery could lead to premature recovery completion, resulting in data loss.

- Prevent errors in WAL replay due to references to uninitialized empty pages (Andres Freund)
- Fix `REINDEX TABLE` and `REINDEX DATABASE` to properly revalidate constraints and mark invalidated indexes as valid (Noah Misch)

`REINDEX INDEX` has always worked properly.

- Avoid deadlocks during insertion into SP-GiST indexes (Teodor Sigaev)
- Fix possible deadlock during concurrent `CREATE INDEX CONCURRENTLY` operations (Tom Lane)
- Fix GiST index lookup crash (Tom Lane)
- Fix `regexp_matches()` handling of zero-length matches (Jeevan Chalke)

Previously, zero-length matches like `'^'` could return too many matches.

- Fix crash for overly-complex regular expressions (Heikki Linnakangas)
- Fix regular expression match failures for back references combined with non-greedy quantifiers (Jeevan Chalke)
- Prevent `CREATE FUNCTION` from checking `SET` variables unless function body checking is enabled (Tom Lane)
- Allow `ALTER DEFAULT PRIVILEGES` to operate on schemas without requiring `CREATE` permission (Tom Lane)
- Loosen restriction on keywords used in queries (Tom Lane)

Specifically, lessen keyword restrictions for role names, language names, `EXPLAIN` and `COPY` options, and `SET` values. This allows `COPY ... (FORMAT BINARY)` to work as expected; previously `BINARY` needed to be quoted.

- Print proper line number during `COPY` failure (Heikki Linnakangas)
- Fix `pgp_pub_decrypt()` so it works for secret keys with passwords (Marko Kreen)
- Make `pg_upgrade` use `pg_dump --quote-all-identifiers` to avoid problems with keyword changes between releases (Tom Lane)
- Remove rare inaccurate warning during vacuum of index-less tables (Heikki Linnakangas)
- Ensure that `VACUUM ANALYZE` still runs the `ANALYZE` phase if its attempt to truncate the file is cancelled due to lock conflicts (Kevin Grittner)
- Avoid possible failure when performing transaction control commands (e.g. `ROLLBACK`) in prepared queries (Tom Lane)
- Ensure that floating-point data input accepts standard spellings of “infinity” on all platforms (Tom Lane)

The C99 standard says that allowable spellings are `inf`, `+inf`, `-inf`, `infinity`, `+infinity`, and `-infinity`. Make sure we recognize these even if the platform's `strtod` function doesn't.

- Avoid unnecessary reporting when `track_activities` is off (Tom Lane)
- Expand ability to compare rows to records and arrays (Rafal Rzepecki, Tom Lane)

- Prevent crash when `psql`'s `PSQLRC` variable contains a tilde (Bruce Momjian)
- Add spinlock support for ARM64 (Mark Salter)
- Update time zone data files to `tzdata` release 2013d for DST law changes in Israel, Morocco, Palestine, and Paraguay. Also, historical zone data corrections for Macquarie Island.

## E.102. Release 9.2.4

**Release date:** 2013-04-04

This release contains a variety of fixes from 9.2.3. For information about new features in the 9.2 major release, see Section E.106.

### E.102.1. Migration to Version 9.2.4

A dump/restore is not required for those running 9.2.X.

However, this release corrects several errors in management of GiST indexes. After installing this update, it is advisable to `REINDEX` any GiST indexes that meet one or more of the conditions described below.

Also, if you are upgrading from a version earlier than 9.2.2, see Section E.104.

### E.102.2. Changes

- Fix insecure parsing of server command-line switches (Mitsumasa Kondo, Kyotaro Horiguchi)

A connection request containing a database name that begins with “-” could be crafted to damage or destroy files within the server's data directory, even if the request is eventually rejected. (CVE-2013-1899)

- Reset OpenSSL randomness state in each postmaster child process (Marko Kreen)

This avoids a scenario wherein random numbers generated by `contrib/pgcrypto` functions might be relatively easy for another database user to guess. The risk is only significant when the postmaster is configured with `ssl = on` but most connections don't use SSL encryption. (CVE-2013-1900)

- Make `REPLICATION` privilege checks test current user not authenticated user (Noah Misch)

An unprivileged database user could exploit this mistake to call `pg_start_backup()` or `pg_stop_backup()`, thus possibly interfering with creation of routine backups. (CVE-2013-1901)

- Fix GiST indexes to not use “fuzzy” geometric comparisons when it's not appropriate to do so (Alexander Korotkov)

The core geometric types perform comparisons using “fuzzy” equality, but `gist_box_same` must do exact comparisons, else GiST indexes using it might become inconsistent. After installing this update, users should `REINDEX` any GiST indexes on `box`, `polygon`, `circle`, or `point` columns, since all of these use `gist_box_same`.

- Fix erroneous range-union and penalty logic in GiST indexes that use `contrib/btree_gist` for variable-width data types, that is `text`, `bytea`, `bit`, and `numeric` columns (Tom Lane)

These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in useless index bloat. Users are advised to `REINDEX` such indexes after installing this update.

- Fix bugs in GiST page splitting code for multi-column indexes (Tom Lane)

These errors could result in inconsistent indexes in which some keys that are present would not be found by searches, and also in indexes that are unnecessarily inefficient to search. Users are advised to `REINDEX` multi-column GiST indexes after installing this update.

- Fix `gist_point_consistent` to handle fuzziness consistently (Alexander Korotkov)

Index scans on GiST indexes on `point` columns would sometimes yield results different from a sequential scan, because `gist_point_consistent` disagreed with the underlying operator code about whether to do comparisons exactly or fuzzily.

- Fix buffer leak in WAL replay (Heikki Linnakangas)

This bug could result in “incorrect local pin count” errors during replay, making recovery impossible.

- Ensure we do crash recovery before entering archive recovery, if the database was not stopped cleanly and a `recovery.conf` file is present (Heikki Linnakangas, Kyotaro Horiguchi, Mitsumasa Kondo)

This is needed to ensure that the database is consistent in certain scenarios, such as initializing a standby server with a filesystem snapshot from a running server.

- Avoid deleting not-yet-archived WAL files during crash recovery (Heikki Linnakangas, Fujii Masao)
- Fix race condition in `DELETE RETURNING` (Tom Lane)

Under the right circumstances, `DELETE RETURNING` could attempt to fetch data from a shared buffer that the current process no longer has any pin on. If some other process changed the buffer meanwhile, this would lead to garbage `RETURNING` output, or even a crash.

- Fix infinite-loop risk in regular expression compilation (Tom Lane, Don Porter)
- Fix potential null-pointer dereference in regular expression compilation (Tom Lane)
- Fix `to_char()` to use ASCII-only case-folding rules where appropriate (Tom Lane)

This fixes misbehavior of some template patterns that should be locale-independent, but mishandled “I” and “i” in Turkish locales.

- Fix unwanted rejection of timestamp `1999-12-31 24:00:00` (Tom Lane)
- Fix SQL-language functions to be safely usable as support functions for range types (Tom Lane)
- Fix logic error when a single transaction does `UNLISTEN` then `LISTEN` (Tom Lane)

The session wound up not listening for notify events at all, though it surely should listen in this case.

- Fix possible planner crash after columns have been added to a view that's depended on by another view (Tom Lane)
- Fix performance issue in `EXPLAIN (ANALYZE, TIMING OFF)` (Pavel Stehule)
- Remove useless “picksplit doesn't support secondary split” log messages (Josh Hansen, Tom Lane)

This message seems to have been added in expectation of code that was never written, and probably never will be, since GiST's default handling of secondary splits is actually pretty good. So stop nagging end users about it.

- Remove vestigial secondary-split support in `gist_box_picksplit()` (Tom Lane)

Not only was this implementation of secondary-split not better than the default implementation, it's actually worse. So remove it and let the default code path handle the case.

- Fix possible failure to send a session's last few transaction commit/abort counts to the statistics collector (Tom Lane)
- Eliminate memory leaks in PL/Perl's `spi_prepare()` function (Alex Hunsaker, Tom Lane)
- Fix `pg_dumpall` to handle database names containing “=” correctly (Heikki Linnakangas)
- Avoid crash in `pg_dump` when an incorrect connection string is given (Heikki Linnakangas)
- Ignore invalid indexes in `pg_dump` and `pg_upgrade` (Michael Paquier, Bruce Momjian)

Dumping invalid indexes can cause problems at restore time, for example if the reason the index creation failed was because it tried to enforce a uniqueness condition not satisfied by the table's data. Also, if the index creation is in fact still in progress, it seems reasonable to consider it to be an uncommitted DDL change, which `pg_dump` wouldn't be expected to dump anyway. `pg_upgrade` now also skips invalid indexes rather than failing.

- In `pg_basebackup`, include only the current server version's subdirectory when backing up a tablespace (Heikki Linnakangas)
- Add a server version check in `pg_basebackup` and `pg_receivexlog`, so they fail cleanly with version combinations that won't work (Heikki Linnakangas)
- Fix `contrib/dblink` to handle inconsistent settings of `DateStyle` or `IntervalStyle` safely (Daniel Farina, Tom Lane)

Previously, if the remote server had different settings of these parameters, ambiguous dates might be read incorrectly. This fix ensures that `datetime` and `interval` columns fetched by a `dblink` query will be interpreted correctly. Note however that inconsistent settings are still risky, since literal values appearing in SQL commands sent to the remote server might be interpreted differently than they would be locally.

- Fix `contrib/pg_trgm`'s `similarity()` function to return zero for trigram-less strings (Tom Lane)

Previously it returned `NaN` due to internal division by zero.

- Enable building PostgreSQL with Microsoft Visual Studio 2012 (Brar Piening, Noah Misch)
- Update time zone data files to `tzdata` release 2013b for DST law changes in Chile, Haiti, Morocco, Paraguay, and some Russian areas. Also, historical zone data corrections for numerous places.

Also, update the time zone abbreviation files for recent changes in Russia and elsewhere: `CHOT`, `GET`, `IRKT`, `KGT`, `KRAT`, `MAGT`, `MAWT`, `MSK`, `NOVT`, `OMST`, `TKT`, `VLAT`, `WST`, `YAKT`, `YEKT` now follow their current meanings, and `VOLT` (Europe/Volgograd) and `MIST` (Antarctica/Macquarie) are added to the default abbreviations list.

## E.103. Release 9.2.3

**Release date:** 2013-02-07

This release contains a variety of fixes from 9.2.2. For information about new features in the 9.2 major release, see Section E.106.

### E.103.1. Migration to Version 9.2.3

A dump/restore is not required for those running 9.2.X.

However, if you are upgrading from a version earlier than 9.2.2, see Section E.104.

### E.103.2. Changes

- Prevent execution of `enum_recv` from SQL (Tom Lane)

The function was misdeclared, allowing a simple SQL command to crash the server. In principle an attacker might be able to use it to examine the contents of server memory. Our thanks to Sumit Soni (via Secunia SVCRP) for reporting this issue. (CVE-2013-0255)

- Fix multiple problems in detection of when a consistent database state has been reached during WAL replay (Fujii Masao, Heikki Linnakangas, Simon Riggs, Andres Freund)
- Fix detection of end-of-backup point when no actual redo work is required (Heikki Linnakangas)

This mistake could result in incorrect “WAL ends before end of online backup” errors.

- Update minimum recovery point when truncating a relation file (Heikki Linnakangas)

Once data has been discarded, it's no longer safe to stop recovery at an earlier point in the timeline.

- Fix recycling of WAL segments after changing recovery target timeline (Heikki Linnakangas)
- Properly restore timeline history files from archive on cascading standby servers (Heikki Linnakangas)
- Fix lock conflict detection on hot-standby servers (Andres Freund, Robert Haas)
- Fix missing cancellations in hot standby mode (Noah Misch, Simon Riggs)

The need to cancel conflicting hot-standby queries would sometimes be missed, allowing those queries to see inconsistent data.

- Prevent recovery pause feature from pausing before users can connect (Tom Lane)
- Fix SQL grammar to allow subscribing or field selection from a sub-SELECT result (Tom Lane)
- Fix performance problems with autovacuum truncation in busy workloads (Jan Wieck)

Truncation of empty pages at the end of a table requires exclusive lock, but autovacuum was coded to fail (and release the table lock) when there are conflicting lock requests. Under load, it is easily possible that truncation would never occur, resulting in table bloat. Fix by performing a partial truncation, releasing the lock, then attempting to re-acquire the lock and continue. This fix also greatly reduces the average time before autovacuum releases the lock after a conflicting request arrives.

- Improve performance of `SPI_execute` and related functions, thereby improving PL/pgSQL's `EXECUTE` (Heikki Linnakangas, Tom Lane)

Remove some data-copying overhead that was added in 9.2 as a consequence of revisions in the plan caching mechanism. This eliminates a performance regression compared to 9.1, and also saves memory, especially when the query string to be executed contains many SQL statements.

A side benefit is that multi-statement query strings are now processed fully serially, that is we complete execution of earlier statements before running parse analysis and planning on the following ones. This eliminates a long-standing issue, in that DDL that should affect the behavior of a later statement will now behave as expected.

- Restore pre-9.2 cost estimates for index usage (Tom Lane)

An ill-considered change of a fudge factor led to undesirably high cost estimates for use of very large indexes.

- Fix intermittent crash in `DROP INDEX CONCURRENTLY` (Tom Lane)
- Fix potential corruption of shared-memory lock table during `CREATE/DROP INDEX CONCURRENTLY` (Tom Lane)
- Fix `COPY`'s multiple-tuple-insertion code for the case of a tuple larger than page size minus fillfactor (Heikki Linnakangas)

The previous coding could get into an infinite loop.

- Protect against race conditions when scanning `pg_tablespace` (Stephen Frost, Tom Lane)

`CREATE DATABASE` and `DROP DATABASE` could misbehave if there were concurrent updates of `pg_tablespace` entries.

- Prevent `DROP OWNED` from trying to drop whole databases or tablespaces (Álvaro Herrera)

For safety, ownership of these objects must be reassigned, not dropped.

- Fix error in `vacuum_freeze_table_age` implementation (Andres Freund)

In installations that have existed for more than `vacuum_freeze_min_age` transactions, this mistake prevented autovacuum from using partial-table scans, so that a full-table scan would always happen instead.

- Prevent misbehavior when a `RowExpr` or `XmlExpr` is parse-analyzed twice (Andres Freund, Tom Lane)

This mistake could be user-visible in contexts such as `CREATE TABLE LIKE INCLUDING INDEXES`.

- Improve defenses against integer overflow in hashtable sizing calculations (Jeff Davis)
- Fix some bugs associated with privileges on datatypes (Tom Lane)

There were some issues with default privileges for types, and `pg_dump` failed to dump such privileges at all.

- Fix failure to ignore leftover temporary tables after a server crash (Tom Lane)
- Fix failure to rotate postmaster log files for size reasons on Windows (Jeff Janes, Heikki Linnakangas)
- Reject out-of-range dates in `to_date()` (Hitoshi Harada)
- Fix `pg_extension_config_dump()` to handle extension-update cases properly (Tom Lane)

This function will now replace any existing entry for the target table, making it usable in extension update scripts.

- Fix PL/pgSQL's reporting of plan-time errors in possibly-simple expressions (Tom Lane)

The previous coding resulted in sometimes omitting the first line in the `CONTEXT` traceback for the error.

- Fix PL/Python's handling of functions used as triggers on multiple tables (Andres Freund)
- Ensure that non-ASCII prompt strings are translated to the correct code page on Windows (Alexander Law, Noah Misch)

This bug affected `psql` and some other client programs.

- Fix possible crash in `psql`'s `\?` command when not connected to a database (Meng Qingzhong)
- Fix possible error if a relation file is removed while `pg_basebackup` is running (Heikki Linnakangas)
- Tolerate timeline switches while `pg_basebackup -X fetch` is backing up a standby server (Heikki Linnakangas)
- Make `pg_dump` exclude data of unlogged tables when running on a hot-standby server (Magnus Hagander)

This would fail anyway because the data is not available on the standby server, so it seems most convenient to assume `--no-unlogged-table-data` automatically.

- Fix `pg_upgrade` to deal with invalid indexes safely (Bruce Momjian)
- Fix `pg_upgrade`'s `-O/-o` options (Marti Raudsepp)
- Fix one-byte buffer overrun in `libpq`'s `PQprintTuples` (Xi Wang)

This ancient function is not used anywhere by PostgreSQL itself, but it might still be used by some client code.

- Make `ecpglib` use translated messages properly (Chen Huajun)
- Properly install `ecpg_compat` and `pgtypes` libraries on MSVC (Jiang Guiqing)
- Include our version of `isinf()` in `libecpg` if it's not provided by the system (Jiang Guiqing)

- Rearrange configure's tests for supplied functions so it is not fooled by bogus exports from libedit/libreadline (Christoph Berg)
- Ensure Windows build number increases over time (Magnus Hagander)
- Make pgxs build executables with the right `.exe` suffix when cross-compiling for Windows (Zoltan Boszormenyi)
- Add new timezone abbreviation `FET` (Tom Lane)

This is now used in some eastern-European time zones.

## E.104. Release 9.2.2

**Release date:** 2012-12-06

This release contains a variety of fixes from 9.2.1. For information about new features in the 9.2 major release, see Section E.106.

### E.104.1. Migration to Version 9.2.2

A dump/restore is not required for those running 9.2.X.

However, you may need to perform `REINDEX` operations to correct problems in concurrently-built indexes, as described in the first changelog item below.

Also, if you are upgrading from version 9.2.0, see Section E.105.

### E.104.2. Changes

- Fix multiple bugs associated with `CREATE/DROP INDEX CONCURRENTLY` (Andres Freund, Tom Lane, Simon Riggs, Pavan Deolasee)

An error introduced while adding `DROP INDEX CONCURRENTLY` allowed incorrect indexing decisions to be made during the initial phase of `CREATE INDEX CONCURRENTLY`; so that indexes built by that command could be corrupt. It is recommended that indexes built in 9.2.X with `CREATE INDEX CONCURRENTLY` be rebuilt after applying this update.

In addition, fix `CREATE/DROP INDEX CONCURRENTLY` to use in-place updates when changing the state of an index's `pg_index` row. This prevents race conditions that could cause concurrent sessions to miss updating the target index, thus again resulting in corrupt concurrently-created indexes.

Also, fix various other operations to ensure that they ignore invalid indexes resulting from a failed `CREATE INDEX CONCURRENTLY` command. The most important of these is `VACUUM`, because an auto-vacuum could easily be launched on the table before corrective action can be taken to fix or remove the invalid index.

Also fix `DROP INDEX CONCURRENTLY` to not disable insertions into the target index until all queries using it are done.

Also fix misbehavior if `DROP INDEX CONCURRENTLY` is canceled: the previous coding could leave an un-droppable index behind.

- Correct predicate locking for `DROP INDEX CONCURRENTLY` (Kevin Grittner)

Previously, SSI predicate locks were processed at the wrong time, possibly leading to incorrect behavior of serializable transactions executing in parallel with the `DROP`.

- Fix buffer locking during WAL replay (Tom Lane)

The WAL replay code was insufficiently careful about locking buffers when replaying WAL records that affect more than one page. This could result in hot standby queries transiently seeing inconsistent states, resulting in wrong answers or unexpected failures.

- Fix an error in WAL generation logic for GIN indexes (Tom Lane)

This could result in index corruption, if a torn-page failure occurred.

- Fix an error in WAL replay logic for SP-GiST indexes (Tom Lane)

This could result in index corruption after a crash, or on a standby server.

- Fix incorrect detection of end-of-base-backup location during WAL recovery (Heikki Linnakangas)

This mistake allowed hot standby mode to start up before the database reaches a consistent state.

- Properly remove startup process's virtual XID lock when promoting a hot standby server to normal running (Simon Riggs)

This oversight could prevent subsequent execution of certain operations such as `CREATE INDEX CONCURRENTLY`.

- Avoid bogus “out-of-sequence timeline ID” errors in standby mode (Heikki Linnakangas)

- Prevent the postmaster from launching new child processes after it's received a shutdown signal (Tom Lane)

This mistake could result in shutdown taking longer than it should, or even never completing at all without additional user action.

- Fix the sysloger process to not fail when `log_rotation_age` exceeds  $2^{31}$  milliseconds (about 25 days) (Tom Lane)

- Fix `WaitLatch()` to return promptly when the requested timeout expires (Jeff Janes, Tom Lane)

With the previous coding, a steady stream of non-wait-terminating interrupts could delay return from `WaitLatch()` indefinitely. This has been shown to be a problem for the autovacuum launcher process, and might cause trouble elsewhere as well.

- Avoid corruption of internal hash tables when out of memory (Hitoshi Harada)
- Prevent file descriptors for dropped tables from being held open past transaction end (Tom Lane)

This should reduce problems with long-since-dropped tables continuing to occupy disk space.

- Prevent database-wide crash and restart when a new child process is unable to create a pipe for its latch (Tom Lane)

Although the new process must fail, there is no good reason to force a database-wide restart, so avoid that. This improves robustness when the kernel is nearly out of file descriptors.

- Avoid planner crash with joins to unflattened subqueries (Tom Lane)
- Fix planning of non-strict equivalence clauses above outer joins (Tom Lane)

The planner could derive incorrect constraints from a clause equating a non-strict construct to something else, for example `WHERE COALESCE(foo, 0) = 0` when `foo` is coming from the nullable side of an outer join. 9.2 showed this type of error in more cases than previous releases, but the basic bug has been there for a long time.

- Fix `SELECT DISTINCT` with index-optimized `MIN/MAX` on an inheritance tree (Tom Lane)

The planner would fail with “failed to re-find MinMaxAggInfo record” given this combination of factors.

- Make sure the planner sees implicit and explicit casts as equivalent for all purposes, except in the minority of cases where there's actually a semantic difference (Tom Lane)
- Include join clauses when considering whether partial indexes can be used for a query (Tom Lane)

A strict join clause can be sufficient to establish an `x IS NOT NULL` predicate, for example. This fixes a planner regression in 9.2, since previous versions could make comparable deductions.

- Limit growth of planning time when there are many indexable join clauses for the same index (Tom Lane)
- Improve planner's ability to prove exclusion constraints from equivalence classes (Tom Lane)
- Fix partial-row matching in hashed subplans to handle cross-type cases correctly (Tom Lane)

This affects multicolumn `NOT IN` subplans, such as `WHERE (a, b) NOT IN (SELECT x, y FROM ...)` when for instance `b` and `y` are `int4` and `int8` respectively. This mistake led to wrong answers or crashes depending on the specific datatypes involved.

- Fix btree mark/restore functions to handle array keys (Tom Lane)

This oversight could result in wrong answers from merge joins whose inner side is an index scan using an `indexed_column = ANY(array)` condition.

- Revert patch for taking fewer snapshots (Tom Lane)

The 9.2 change to reduce the number of snapshots taken during query execution led to some anomalous behaviors not seen in previous releases, because execution would proceed with a snapshot acquired before locking the tables used by the query. Thus, for example, a query would not be guaranteed to see updates committed by a preceding transaction even if that transaction had exclusive lock. We'll probably revisit this in future releases, but meanwhile put it back the way it was before 9.2.

- Acquire buffer lock when re-fetching the old tuple for an `AFTER ROW UPDATE/DELETE` trigger (Andres Freund)

In very unusual circumstances, this oversight could result in passing incorrect data to a trigger `WHEN` condition, or to the precheck logic for a foreign-key enforcement trigger. That could result in a crash, or in an incorrect decision about whether to fire the trigger.

- Fix `ALTER COLUMN TYPE` to handle inherited check constraints properly (Pavan Deolasee)

This worked correctly in pre-8.4 releases, and now works correctly in 8.4 and later.

- Fix `ALTER EXTENSION SET SCHEMA`'s failure to move some subsidiary objects into the new schema (Álvaro Herrera, Dimitri Fontaine)
- Handle `CREATE TABLE AS EXECUTE` correctly in extended query protocol (Tom Lane)
- Don't modify the input parse tree in `DROP RULE IF NOT EXISTS` and `DROP TRIGGER IF NOT EXISTS` (Tom Lane)

This mistake would cause errors if a cached statement of one of these types was re-executed.

- Fix `REASSIGN OWNED` to handle grants on tablespaces (Álvaro Herrera)
- Ignore incorrect `pg_attribute` entries for system columns for views (Tom Lane)

Views do not have any system columns. However, we forgot to remove such entries when converting a table to a view. That's fixed properly for 9.3 and later, but in previous branches we need to defend against existing mis-converted views.

- Fix rule printing to dump `INSERT INTO table DEFAULT VALUES` correctly (Tom Lane)
- Guard against stack overflow when there are too many `UNION/INTERSECT/EXCEPT` clauses in a query (Tom Lane)
- Prevent platform-dependent failures when dividing the minimum possible integer value by -1 (Xi Wang, Tom Lane)
- Fix possible access past end of string in date parsing (Hitoshi Harada)
- Fix failure to advance XID epoch if XID wraparound happens during a checkpoint and `wal_level` is `hot_standby` (Tom Lane, Andres Freund)

While this mistake had no particular impact on PostgreSQL itself, it was bad for applications that rely on `txid_current()` and related functions: the TXID value would appear to go backwards.

- Fix `pg_terminate_backend()` and `pg_cancel_backend()` to not throw error for a non-existent target process (Josh KuperShmidt)

This case already worked as intended when called by a superuser, but not so much when called by ordinary users.

- Fix display of `pg_stat_replication.sync_state` at a page boundary (Kyotaro Horiguchi)
- Produce an understandable error message if the length of the path name for a Unix-domain socket exceeds the platform-specific limit (Tom Lane, Andrew Dunstan)

Formerly, this would result in something quite unhelpful, such as “Non-recoverable failure in name resolution”.

- Fix memory leaks when sending composite column values to the client (Tom Lane)
- Save some cycles by not searching for subtransaction locks at commit (Simon Riggs)

In a transaction holding many exclusive locks, this useless activity could be quite costly.

- Make `pg_ctl` more robust about reading the `postmaster.pid` file (Heikki Linnakangas)

This fixes race conditions and possible file descriptor leakage.

- Fix possible crash in `psql` if incorrectly-encoded data is presented and the `client_encoding` setting is a client-only encoding, such as SJIS (Jiang Guiqing)
- Make `pg_dump` dump `SEQUENCE SET` items in the data not pre-data section of the archive (Tom Lane)

This fixes an undesirable inconsistency between the meanings of `--data-only` and `--section=data`, and also fixes dumping of sequences that are marked as extension configuration tables.

- Fix `pg_dump`'s handling of `DROP DATABASE` commands in `--clean` mode (Guillaume Lelarge)

Beginning in 9.2.0, `pg_dump --clean` would issue a `DROP DATABASE` command, which was either useless or dangerous depending on the usage scenario. It no longer does that. This change also fixes the combination of `--clean` and `--create` to work sensibly, i.e., emit `DROP DATABASE` then `CREATE DATABASE` before reconnecting to the target database.

- Fix `pg_dump` for views with circular dependencies and no relation options (Tom Lane)

The previous fix to dump relation options when a view is involved in a circular dependency didn't work right for the case that the view has no options; it emitted `ALTER VIEW foo SET ()` which is invalid syntax.

- Fix bugs in the `restore.sql` script emitted by `pg_dump` in `tar` output format (Tom Lane)

The script would fail outright on tables whose names include upper-case characters. Also, make the script capable of restoring data in `--inserts` mode as well as the regular `COPY` mode.

- Fix `pg_restore` to accept POSIX-conformant `tar` files (Brian Weaver, Tom Lane)

The original coding of `pg_dump`'s `tar` output mode produced files that are not fully conformant with the POSIX standard. This has been corrected for version 9.3. This patch updates previous branches so that they will accept both the incorrect and the corrected formats, in hopes of avoiding compatibility problems when 9.3 comes out.

- Fix `tar` files emitted by `pg_basebackup` to be POSIX conformant (Brian Weaver, Tom Lane)
- Fix `pg_resetxlog` to locate `postmaster.pid` correctly when given a relative path to the data directory (Tom Lane)

This mistake could lead to `pg_resetlog` not noticing that there is an active postmaster using the data directory.

- Fix `libpq`'s `lo_import()` and `lo_export()` functions to report file I/O errors properly (Tom Lane)
- Fix `ecpg`'s processing of nested structure pointer variables (Muhammad Usama)
- Fix `ecpg`'s `ecpg_get_data` function to handle arrays properly (Michael Meskes)
- Prevent `pg_upgrade` from trying to process TOAST tables for system catalogs (Bruce Momjian)

This fixes an error seen when the `information_schema` has been dropped and recreated. Other failures were also possible.

- Improve `pg_upgrade` performance by setting `synchronous_commit` to `off` in the new cluster (Bruce Momjian)
- Make `contrib/pageinspect`'s btree page inspection functions take buffer locks while examining pages (Tom Lane)
- Work around unportable behavior of `malloc(0)` and `realloc(NULL, 0)` (Tom Lane)

On platforms where these calls return `NULL`, some code mistakenly thought that meant out-of-memory. This is known to have broken `pg_dump` for databases containing no user-defined aggregates. There might be other cases as well.

- Ensure that `make install` for an extension creates the `extension` installation directory (Cédric Villemain)

Previously, this step was missed if `MODULEDIR` was set in the extension's Makefile.

- Fix `pgxs` support for building loadable modules on AIX (Tom Lane)

Building modules outside the original source tree didn't work on AIX.

- Update time zone data files to `tzdata` release 2012j for DST law changes in Cuba, Israel, Jordan, Libya, Palestine, Western Samoa, and portions of Brazil.

## E.105. Release 9.2.1

**Release date:** 2012-09-24

This release contains a variety of fixes from 9.2.0. For information about new features in the 9.2 major release, see Section E.106.

### E.105.1. Migration to Version 9.2.1

A dump/restore is not required for those running 9.2.X.

However, you may need to perform `REINDEX` and/or `VACUUM` operations to recover from the effects of the data corruption bug described in the first changelog item below.

### E.105.2. Changes

- Fix persistence marking of shared buffers during WAL replay (Jeff Davis)

This mistake can result in buffers not being written out during checkpoints, resulting in data corruption if the server later crashes without ever having written those buffers. Corruption can occur on any server following crash recovery, but it is significantly more likely to occur on standby slave servers since those perform much more WAL replay. There is a low probability of corruption of btree and GIN indexes. There is a much higher probability of corruption of table “visibility maps”, which might lead to wrong answers from index-only scans. Table data proper cannot be corrupted by this bug.

While no index corruption due to this bug is known to have occurred in the field, as a precautionary measure it is recommended that production installations `REINDEX` all btree and GIN indexes at a convenient time after upgrading to 9.2.1.

Also, it is recommended to perform a `VACUUM` of all tables while having `vacuum_freeze_table_age` set to zero. This will fix any incorrect visibility map data. `vacuum_cost_delay` can be adjusted to reduce the performance impact of vacuuming, while causing it to take longer to finish.

- Fix possible incorrect sorting of output from queries involving `WHERE indexed_column IN (list_of_values)` (Tom Lane)
- Fix planner failure for queries involving `GROUP BY` expressions along with window functions and aggregates (Tom Lane)
- Fix planner's assignment of executor parameters (Tom Lane)

This error could result in wrong answers from queries that scan the same `WITH` subquery multiple times.

- Improve planner's handling of join conditions in index scans (Tom Lane)
- Improve selectivity estimation for text search queries involving prefixes, i.e. `word:*` patterns (Tom Lane)
- Fix delayed recognition of permissions changes (Tom Lane)

A command that needed no locks other than ones its transaction already had might fail to notice a concurrent `GRANT` or `REVOKE` that committed since the start of its transaction.

- Fix `ANALYZE` to not fail when a column is a domain over an array type (Tom Lane)
- Prevent PL/Perl from crashing if a recursive PL/Perl function is redefined while being executed (Tom Lane)
- Work around possible misoptimization in PL/Perl (Tom Lane)

Some Linux distributions contain an incorrect version of `pthread.h` that results in incorrect compiled code in PL/Perl, leading to crashes if a PL/Perl function calls another one that throws an error.

- Remove unnecessary dependency on `pg_config` from `pg_upgrade` (Peter Eisentraut)
- Update time zone data files to tzdata release 2012f for DST law changes in Fiji

## E.106. Release 9.2

**Release date:** 2012-09-10

### E.106.1. Overview

This release has been largely focused on performance improvements, though new SQL features are not lacking. Work also continues in the area of replication support. Major enhancements include:

- Allow queries to retrieve data only from indexes, avoiding heap access (*index-only scans*)
- Allow the planner to generate custom plans for specific parameter values even when using prepared statements
- Improve the planner's ability to use nested loops with inner index scans
- Allow streaming replication slaves to forward data to other slaves (*cascading replication*)
- Allow `pg_basebackup` to make base backups from standby servers
- Add a `pg_receivexlog` tool to archive WAL file changes as they are written
- Add the SP-GiST (Space-Partitioned GiST) index access method

- Add support for range data types
- Add a `JSON` data type
- Add a `security_barrier` option for views
- Allow libpq connection strings to have the format of a URI
- Add a single-row processing mode to libpq for better handling of large result sets

The above items are explained in more detail in the sections below.

## E.106.2. Migration to Version 9.2

A dump/restore using `pg_dump`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.2 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

### E.106.2.1. System Catalogs

- Remove the `spclocation` field from `pg_tablespace` (Magnus Hagander)

This field was duplicative of the symbolic links that actually define tablespace locations, and thus risked errors of omission when moving a tablespace. This change allows tablespace directories to be moved while the server is down, by manually adjusting the symbolic links. To replace this field, we have added `pg_tablespace_location()` to allow querying of the symbolic links.

- Move `tsvector` most-common-element statistics to new `pg_stats` columns (Alexander Korotkov)

Consult `most_common_elems` and `most_common_elem_freqs` for the data formerly available in `most_common_vals` and `most_common_freqs` for a `tsvector` column.

### E.106.2.2. Functions

- Remove `hstore`'s `=>` operator (Robert Haas)

Users should now use `hstore(text, text)`. Since PostgreSQL 9.0, a warning message has been emitted when an operator named `=>` is created because the SQL standard reserves that token for another use.

- Ensure that `xpath()` escapes special characters in string values (Florian Pflug)

Without this it is possible for the result not to be valid XML.

- Make `pg_relation_size()` and friends return `NULL` if the object does not exist (Phil Sorber)

This prevents queries that call these functions from returning errors immediately after a concurrent `DROP`.

- Make `EXTRACT(EPOCH FROM timestamp without time zone)` measure the epoch from local midnight, not UTC midnight (Tom Lane)

This change reverts an ill-considered change made in release 7.3. Measuring from UTC midnight was inconsistent because it made the result dependent on the `timezone` setting, which computations for `timestamp without time zone` should not be. The previous behavior remains available by casting the input value to `timestamp with time zone`.

- Properly parse time strings with trailing `yesterday`, `today`, and `tomorrow` (Dean Rasheed)

Previously, `SELECT '04:00:00 yesterday'::timestamp` returned yesterday's date at midnight.

- Fix `to_date()` and `to_timestamp()` to wrap incomplete dates toward 2020 (Bruce Momjian)

Previously, supplied years and year masks of less than four digits wrapped inconsistently.

### E.106.2.3. Object Modification

- Prevent `ALTER DOMAIN` from working on non-domain types (Peter Eisentraut)

Owner and schema changes were previously possible on non-domain types.

- No longer forcibly lowercase procedural language names in `CREATE FUNCTION` (Robert Haas)

While unquoted language identifiers are still lowercased, strings and quoted identifiers are no longer forcibly down-cased. Thus for example `CREATE FUNCTION ... LANGUAGE 'C'` will no longer work; it must be spelled `'c'`, or better omit the quotes.

- Change system-generated names of foreign key enforcement triggers (Tom Lane)

This change ensures that the triggers fire in the correct order in some corner cases involving self-referential foreign key constraints.

### E.106.2.4. Command-Line Tools

- Provide consistent backquote, variable expansion, and quoted substring behavior in `psql` meta-command arguments (Tom Lane)

Previously, such references were treated oddly when not separated by whitespace from adjacent text. For example `'FOO'BAR` was output as `FOO BAR` (unexpected insertion of a space) and `FOO'BAR'BAZ` was output unchanged (not removing the quotes as most would expect).

- No longer treat clusterdb table names as double-quoted; no longer treat reindexdb table and index names as double-quoted (Bruce Momjian)

Users must now include double-quotes in the command arguments if quoting is wanted.

- `createuser` no longer prompts for option settings by default (Peter Eisentraut)

Use `--interactive` to obtain the old behavior.

- Disable prompting for the user name in `dropuser` unless `--interactive` is specified (Peter Eisentraut)

### E.106.2.5. Server Settings

- Add server parameters for specifying the locations of server-side SSL files (Peter Eisentraut)

This allows changing the names and locations of the files that were previously hard-coded as `server.crt`, `server.key`, `root.crt`, and `root.crl` in the data directory. *The server will no longer examine `root.crt` or `root.crl` by default*; to load these files, the associated parameters must be set to non-default values.

- Remove the `silent_mode` parameter (Heikki Linnakangas)

Similar behavior can be obtained with `pg_ctl start -l postmaster.log`.

- Remove the `wal_sender_delay` parameter, as it is no longer needed (Tom Lane)
- Remove the `custom_variable_classes` parameter (Tom Lane)

The checking provided by this setting was dubious. Now any setting can be prefixed by any class name.

### E.106.2.6. Monitoring

- Rename `pg_stat_activity.procpid` to `pid`, to match other system tables (Magnus Hagander)
- Create a separate `pg_stat_activity` column to report process state (Scott Mead, Magnus Hagander)

The previous `query` and `query_start` values now remain available for an idle session, allowing enhanced analysis.

- Rename `pg_stat_activity.current_query` to `query` because it is not cleared when the query completes (Magnus Hagander)
- Change all SQL-level statistics timing values to be `float8` columns measured in milliseconds (Tom Lane)

This change eliminates the designed-in assumption that the values are accurate to microseconds and no more (since the `float8` values can be fractional). The columns affected are `pg_stat_user_functions.total_time`, `pg_stat_user_functions.self_time`, `pg_stat_xact_user_functions.total_time`, and `pg_stat_xact_user_functions.self_time`. The statistics functions underlying these columns now also return `float8` milliseconds, rather than `bigint` microseconds. `contrib/pg_stat_statements`' `total_time` column is now also measured in milliseconds.

### E.106.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.2 and the previous major release.

#### E.106.3.1. Server

##### E.106.3.1.1. Performance

- Allow queries to retrieve data only from indexes, avoiding heap access (Robert Haas, Ibrar Ahmed, Heikki Linnakangas, Tom Lane)

This feature is often called *index-only scans*. Heap access can be skipped for heap pages containing only tuples that are visible to all sessions, as reported by the visibility map; so the benefit applies mainly to mostly-static data. The visibility map was made crash-safe as a necessary part of implementing this feature.

- Add the SP-GiST (Space-Partitioned GiST) index access method (Teodor Sigaev, Oleg Bartunov, Tom Lane)

SP-GiST is comparable to GiST in flexibility, but supports unbalanced partitioned search structures rather than balanced trees. For suitable problems, SP-GiST can be faster than GiST in both index build time and search time.

- Allow group commit to work effectively under heavy load (Peter Geoghegan, Simon Riggs, Heikki Linnakangas)

Previously, batching of commits became ineffective as the write workload increased, because of internal lock contention.

- Allow uncontended locks to be managed using a new fast-path lock mechanism (Robert Haas)
- Reduce overhead of creating virtual transaction ID locks (Robert Haas)
- Reduce the overhead of serializable isolation level locks (Dan Ports)
- Improve PowerPC and Itanium spinlock performance (Manabu Ori, Robert Haas, Tom Lane)
- Reduce overhead for shared invalidation cache messages (Robert Haas)
- Move the frequently accessed members of the `PGPROC` shared memory array to a separate array (Pavan Deolasee, Heikki Linnakangas, Robert Haas)
- Improve `COPY` performance by adding tuples to the heap in batches (Heikki Linnakangas)
- Improve GiST index performance for geometric data types by producing better trees with less memory allocation overhead (Alexander Korotkov)
- Improve GiST index build times (Alexander Korotkov, Heikki Linnakangas)
- Allow hint bits to be set sooner for temporary and unlogged tables (Robert Haas)

- Allow sorting to be performed by inlined, non-SQL-callable comparison functions (Peter Geoghegan, Robert Haas, Tom Lane)
- Make the number of CLOG buffers scale based on `shared_buffers` (Robert Haas, Simon Riggs, Tom Lane)
- Improve performance of buffer pool scans that occur when tables or databases are dropped (Jeff Janes, Simon Riggs)
- Improve performance of checkpoint's fsync-request queue when many tables are being dropped or truncated (Tom Lane)
- Pass the safe number of file descriptors to child processes on Windows (Heikki Linnakangas)

This allows Windows sessions to use more open file descriptors than before.

#### **E.106.3.1.2. Process Management**

- Create a dedicated background process to perform checkpoints (Simon Riggs)

Formerly the background writer did both dirty-page writing and checkpointing. Separating this into two processes allows each goal to be accomplished more predictably.

- Improve asynchronous commit behavior by waking the walwriter sooner (Simon Riggs)

Previously, only `wal_writer_delay` triggered WAL flushing to disk; now filling a WAL buffer also triggers WAL writes.

- Allow the bgwriter, walwriter, checkpointer, statistics collector, log collector, and archiver background processes to sleep more efficiently during periods of inactivity (Peter Geoghegan, Tom Lane)

This series of changes reduces the frequency of process wake-ups when there is nothing to do, dramatically reducing power consumption on idle servers.

#### **E.106.3.1.3. Optimizer**

- Allow the planner to generate custom plans for specific parameter values even when using prepared statements (Tom Lane)

In the past, a prepared statement always had a single “generic” plan that was used for all parameter values, which was frequently much inferior to the plans used for non-prepared statements containing explicit constant values. Now, the planner attempts to generate custom plans for specific parameter values. A generic plan will only be used after custom plans have repeatedly proven to provide no benefit. This change should eliminate the performance penalties formerly seen from use of prepared statements (including non-dynamic statements in PL/pgSQL).

- Improve the planner's ability to use nested loops with inner index scans (Tom Lane)

The new “parameterized path” mechanism allows inner index scans to use values from relations that are more than one join level up from the scan. This can greatly improve performance in situations where semantic restrictions (such as outer joins) limit the allowed join orderings.

- Improve the planning API for foreign data wrappers (Etsuro Fujita, Shigeru Hanada, Tom Lane)

Wrappers can now provide multiple access “paths” for their tables, allowing more flexibility in join planning.

- Recognize self-contradictory restriction clauses for non-table relations (Tom Lane)

This check is only performed when `constraint_exclusion` is on.

- Allow `indexed_col op ANY(ARRAY[...])` conditions to be used in plain index scans and index-only scans (Tom Lane)

Formerly such conditions could only be used in bitmap index scans.

- Support `MIN/MAX` index optimizations on `boolean` columns (Marti Raudsepp)
- Account for set-returning functions in `SELECT` target lists when setting row count estimates (Tom Lane)
- Fix planner to handle indexes with duplicated columns more reliably (Tom Lane)
- Collect and use element-frequency statistics for arrays (Alexander Korotkov, Tom Lane)

This change improves selectivity estimation for the array `<@, &&, and @>` operators (array containment and overlaps).

- Allow statistics to be collected for foreign tables (Etsuro Fujita)
- Improve cost estimates for use of partial indexes (Tom Lane)
- Improve the planner's ability to use statistics for columns referenced in subqueries (Tom Lane)
- Improve statistical estimates for subqueries using `DISTINCT` (Tom Lane)

#### **E.106.3.1.4. Authentication**

- Do not treat role names and `samerole` specified in `pg_hba.conf` as automatically including superusers (Andrew Dunstan)

This makes it easier to use `reject` lines with group roles.

- Adjust `pg_hba.conf` processing to handle token parsing more consistently (Brendan Jurd, Álvaro Herrera)
- Disallow empty `pg_hba.conf` files (Tom Lane)

This was done to more quickly detect misconfiguration.

- Make superuser privilege imply replication privilege (Noah Misch)

This avoids the need to explicitly assign such privileges.

#### **E.106.3.1.5. Monitoring**

- Attempt to log the current query string during a backend crash (Marti Raudsepp)
- Make logging of autovacuum I/O activity more verbose (Greg Smith, Noah Misch)

This logging is triggered by `log_autovacuum_min_duration`.

- Make WAL replay report failures sooner (Fujii Masao)

There were some cases where failures were only reported once the server went into master mode.

- Add `pg_xlog_location_diff()` to simplify WAL location comparisons (Euler Taveira de Oliveira)

This is useful for computing replication lag.

- Support configurable event log application names on Windows (MauMau, Magnus Hagander)

This allows different instances to use the event log with different identifiers, by setting the `event_source` server parameter, which is similar to how `syslog_ident` works.

- Change “unexpected EOF” messages to `DEBUG1` level, except when there is an open transaction (Magnus Hagander)

This change reduces log chatter caused by applications that close database connections ungracefully.

#### **E.106.3.1.6. Statistical Views**

- Track temporary file sizes and file counts in the `pg_stat_database` system view (Tomas Vondra)

- Add a deadlock counter to the `pg_stat_database` system view (Magnus Hagander)
- Add a server parameter `track_io_timing` to track I/O timings (Ants Aasma, Robert Haas)
- Report checkpoint timing information in `pg_stat_bgwriter` (Greg Smith, Peter Geoghegan)

### E.106.3.1.7. Server Settings

- Silently ignore nonexistent schemas specified in `search_path` (Tom Lane)

This makes it more convenient to use generic path settings, which might include some schemas that don't exist in all databases.

- Allow superusers to set `deadlock_timeout` per-session, not just per-cluster (Noah Misch)

This allows `deadlock_timeout` to be reduced for transactions that are likely to be involved in a deadlock, thus detecting the failure more quickly. Alternatively, increasing the value can be used to reduce the chances of a session being chosen for cancellation due to a deadlock.

- Add a server parameter `temp_file_limit` to constrain temporary file space usage per session (Mark Kirkwood)
- Allow a superuser to `SET` an extension's superuser-only custom variable before loading the associated extension (Tom Lane)

The system now remembers whether a `SET` was performed by a superuser, so that proper privilege checking can be done when the extension is loaded.

- Add postmaster `-C` option to query configuration parameters (Bruce Momjian)

This allows `pg_ctl` to better handle cases where `PGDATA` or `-D` points to a configuration-only directory.

- Replace an empty locale name with the implied value in `CREATE DATABASE` (Tom Lane)

This prevents cases where `pg_database.datcollate` or `datctype` could be interpreted differently after a server restart.

#### E.106.3.1.7.1. `postgresql.conf`

- Allow multiple errors in `postgresql.conf` to be reported, rather than just the first one (Alexey Klyukin, Tom Lane)
- Allow a reload of `postgresql.conf` to be processed by all sessions, even if there are some settings that are invalid for particular sessions (Alexey Klyukin)

Previously, such not-valid-within-session values would cause all setting changes to be ignored by that session.

- Add an `include_if_exists` facility for configuration files (Greg Smith)

This works the same as `include`, except that an error is not thrown if the file is missing.

- Identify the server time zone during `initdb`, and set `postgresql.conf` entries `timezone` and `log_timezone` accordingly (Tom Lane)

This avoids expensive time zone probes during server start.

- Fix `pg_settings` to report `postgresql.conf` line numbers on Windows (Tom Lane)

### E.106.3.2. Replication and Recovery

- Allow streaming replication slaves to forward data to other slaves (*cascading replication*) (Fujii Masao)

Previously, only the master server could supply streaming replication log files to standby servers.

- Add new `synchronous_commit mode remote_write` (Fujii Masao, Simon Riggs)

This mode waits for the standby server to write transaction data to its own operating system, but does not wait for the data to be flushed to the standby's disk.

- Add a `pg_receivexlog` tool to archive WAL file changes as they are written, rather than waiting for completed WAL files (Magnus Hagander)

- Allow `pg_basebackup` to make base backups from standby servers (Jun Ishizuka, Fujii Masao)

This feature lets the work of making new base backups be off-loaded from the primary server.

- Allow streaming of WAL files while `pg_basebackup` is performing a backup (Magnus Hagander)

This allows passing of WAL files to the standby before they are discarded on the primary.

### E.106.3.3. Queries

- Cancel the running query if the client gets disconnected (Florian Pflug)

If the backend detects loss of client connection during a query, it will now cancel the query rather than attempting to finish it.

- Retain column names at run time for row expressions (Andrew Dunstan, Tom Lane)

This change allows better results when a row value is converted to `hstore` or `json` type: the fields of the resulting value will now have the expected names.

- Improve column labels used for sub-`SELECT` results (Marti Raudsepp)

Previously, the generic label `?column?` was used.

- Improve heuristics for determining the types of unknown values (Tom Lane)

The longstanding rule that an unknown constant might have the same type as the value on the other side of the operator using it is now applied when considering polymorphic operators, not only for simple operator matches.

- Warn about creating casts to or from domain types (Robert Haas)

Such casts have no effect.

- When a row fails a `CHECK` or `NOT NULL` constraint, show the row's contents as error detail (Jan Kun-drát)

This should make it easier to identify which row is problematic when an insert or update is processing many rows.

### E.106.3.4. Object Manipulation

- Provide more reliable operation during concurrent DDL (Robert Haas, Noah Misch)

This change adds locking that should eliminate “cache lookup failed” errors in many scenarios. Also, it is no longer possible to add relations to a schema that is being concurrently dropped, a scenario that formerly led to inconsistent system catalog contents.

- Add `CONCURRENTLY` option to `DROP INDEX` (Simon Riggs)

This allows index removal without blocking other sessions.

- Allow foreign data wrappers to have per-column options (Shigeru Hanada)

- Improve pretty-printing of view definitions (Andrew Dunstan)

#### E.106.3.4.1. Constraints

- Allow `CHECK` constraints to be declared `NOT VALID` (Álvaro Herrera)

Adding a `NOT VALID` constraint does not cause the table to be scanned to verify that existing rows meet the constraint. Subsequently, newly added or updated rows are checked. Such constraints are ignored by the planner when considering `constraint_exclusion`, since it is not certain that all rows meet the constraint.

The new `ALTER TABLE VALIDATE` command allows `NOT VALID` constraints to be checked for existing rows, after which they are converted into ordinary constraints.

- Allow `CHECK` constraints to be declared `NO INHERIT` (Nikhil Sontakke, Alex Hunsaker, Álvaro Herrera)

This makes them enforceable only on the parent table, not on child tables.

- Add the ability to rename constraints (Peter Eisentraut)

#### **E.106.3.4.2. ALTER**

- Reduce need to rebuild tables and indexes for certain `ALTER TABLE ... ALTER COLUMN TYPE` operations (Noah Misch)

Increasing the length limit for a `varchar` or `varbit` column, or removing the limit altogether, no longer requires a table rewrite. Similarly, increasing the allowable precision of a `numeric` column, or changing a column from constrained `numeric` to unconstrained `numeric`, no longer requires a table rewrite. Table rewrites are also avoided in similar cases involving the `interval`, `timestamp`, and `timestampz` types.

- Avoid having `ALTER TABLE` revalidate foreign key constraints in some cases where it is not necessary (Noah Misch)
- Add `IF EXISTS` options to some `ALTER` commands (Pavel Stehule)

For example, `ALTER FOREIGN TABLE IF EXISTS foo RENAME TO bar`.

- Add `ALTER FOREIGN DATA WRAPPER ... RENAME` and `ALTER SERVER ... RENAME` (Peter Eisentraut)
- Add `ALTER DOMAIN ... RENAME` (Peter Eisentraut)

You could already rename domains using `ALTER TYPE`.

- Throw an error for `ALTER DOMAIN ... DROP CONSTRAINT` on a nonexistent constraint (Peter Eisentraut)

An `IF EXISTS` option has been added to provide the previous behavior.

#### **E.106.3.4.3. CREATE TABLE**

- Allow `CREATE TABLE (LIKE ...)` from foreign tables, views, and composite types (Peter Eisentraut)

For example, this allows a table to be created whose schema matches a view.

- Fix `CREATE TABLE (LIKE ...)` to avoid index name conflicts when copying index comments (Tom Lane)
- Fix `CREATE TABLE ... AS EXECUTE` to handle `WITH NO DATA` and column name specifications (Tom Lane)

#### **E.106.3.4.4. Object Permissions**

- Add a `security_barrier` option for views (KaiGai Kohei, Robert Haas)

This option prevents optimizations that might allow view-protected data to be exposed to users, for example pushing a clause involving an insecure function into the `WHERE` clause of the view. Such views can be expected to perform more poorly than ordinary views.

- Add a new `LEAKPROOF` function attribute to mark functions that can safely be pushed down into `security_barrier` views (KaiGai Kohei)
- Add support for privileges on data types (Peter Eisentraut)

This adds support for the SQL-conforming `USAGE` privilege on types and domains. The intent is to be able to restrict which users can create dependencies on types, since such dependencies limit the owner's ability to alter the type.

- Check for `INSERT` privileges in `SELECT INTO` / `CREATE TABLE AS` (KaiGai Kohei)

Because the object is being created by `SELECT INTO` or `CREATE TABLE AS`, the creator would ordinarily have insert permissions; but there are corner cases where this is not true, such as when `ALTER DEFAULT PRIVILEGES` has removed such permissions.

### E.106.3.5. Utility Operations

- Allow `VACUUM` to more easily skip pages that cannot be locked (Simon Riggs, Robert Haas)

This change should greatly reduce the incidence of `VACUUM` getting “stuck” waiting for other sessions.

- Make `EXPLAIN (BUFFERS)` count blocks dirtied and written (Robert Haas)
- Make `EXPLAIN ANALYZE` report the number of rows rejected by filter steps (Marko Tiikkaja)
- Allow `EXPLAIN ANALYZE` to avoid timing overhead when time values are not wanted (Tomas Vondra)

This is accomplished by setting the new `TIMING` option to `FALSE`.

### E.106.3.6. Data Types

- Add support for range data types (Jeff Davis, Tom Lane, Alexander Korotkov)

A range data type stores a lower and upper bound belonging to its base data type. It supports operations like contains, overlaps, and intersection.

- Add a `JSON` data type (Robert Haas)

This type stores JSON (JavaScript Object Notation) data with proper validation.

- Add `array_to_json()` and `row_to_json()` (Andrew Dunstan)
- Add a `SMALLSERIAL` data type (Mike Pultz)

This is like `SERIAL`, except it stores the sequence in a two-byte integer column (`int2`).

- Allow domains to be declared `NOT VALID` (Álvaro Herrera)

This option can be set at domain creation time, or via `ALTER DOMAIN ... ADD CONSTRAINT ... NOT VALID`. `ALTER DOMAIN ... VALIDATE CONSTRAINT` fully validates the constraint.

- Support more locale-specific formatting options for the `money` data type (Tom Lane)

Specifically, honor all the POSIX options for ordering of the value, sign, and currency symbol in monetary output. Also, make sure that the thousands separator is only inserted to the left of the decimal point, as required by POSIX.

- Add bitwise “and”, “or”, and “not” operators for the `macaddr` data type (Brendan Jurd)
- Allow `xpath()` to return a single-element XML array when supplied a scalar value (Florian Pflug)

Previously, it returned an empty array. This change will also cause `xpath_exists()` to return true, not false, for such expressions.

- Improve XML error handling to be more robust (Florian Pflug)

### E.106.3.7. Functions

- Allow non-superusers to use `pg_cancel_backend()` and `pg_terminate_backend()` on other sessions belonging to the same user (Magnus Hagander, Josh Kopershmidt, Dan Farina)

Previously only superusers were allowed to use these functions.

- Allow importing and exporting of transaction snapshots (Joachim Wieland, Tom Lane)

This allows multiple transactions to share identical views of the database state. Snapshots are exported via `pg_export_snapshot()` and imported via `SET TRANSACTION SNAPSHOT`. Only snapshots from currently-running transactions can be imported.

- Support `COLLATION FOR` on expressions (Peter Eisentraut)

This returns a string representing the collation of the expression.

- Add `pg_opfamily_is_visible()` (Josh Kopershmidt)
- Add a numeric variant of `pg_size_pretty()` for use with `pg_xlog_location_diff()` (Fujii Masao)
- Add a `pg_trigger_depth()` function (Kevin Grittner)

This reports the current trigger call depth.

- Allow `string_agg()` to process `bytea` values (Pavel Stehule)
- Fix regular expressions in which a back-reference occurs within a larger quantified subexpression (Tom Lane)

For example, `^(\w+)(\1)+$`. Previous releases did not check that the back-reference actually matched the first occurrence.

### E.106.3.8. Information Schema

- Add information schema views `role_udt_grants`, `udt_privileges`, and `user_defined_types` (Peter Eisentraut)
- Add composite-type attributes to the information schema `element_types` view (Peter Eisentraut)
- Implement `interval_type` columns in the information schema (Peter Eisentraut)

Formerly these columns read as nulls.

- Implement collation-related columns in the information schema `attributes`, `columns`, `domains`, and `element_types` views (Peter Eisentraut)
- Implement the `with_hierarchy` column in the information schema `table_privileges` view (Peter Eisentraut)
- Add display of sequence `USAGE` privileges to information schema (Peter Eisentraut)
- Make the information schema show default privileges (Peter Eisentraut)

Previously, non-empty default permissions were not represented in the views.

### E.106.3.9. Server-Side Languages

#### E.106.3.9.1. PL/pgSQL Server-Side Language

- Allow the PL/pgSQL `OPEN` cursor command to supply parameters by name (Yeb Havinga)
- Add a `GET STACKED DIAGNOSTICS` PL/pgSQL command to retrieve exception info (Pavel Stehule)
- Speed up PL/pgSQL array assignment by caching type information (Pavel Stehule)
- Improve performance and memory consumption for long chains of `ELSIF` clauses (Tom Lane)
- Output the function signature, not just the name, in PL/pgSQL error messages (Pavel Stehule)

### E.106.3.9.2. PL/Python Server-Side Language

- Add PL/Python SPI cursor support (Jan Urbanski)

This allows PL/Python to read partial result sets.

- Add result metadata functions to PL/Python (Peter Eisentraut)

Specifically, this adds result object functions `.colnames`, `.coltypes`, and `.coltypmods`.

- Remove support for Python 2.2 (Peter Eisentraut)

### E.106.3.9.3. SQL Server-Side Language

- Allow SQL-language functions to reference parameters by name (Matthew Draper)

To use this, simply name the function arguments and then reference the argument names in the SQL function body.

### E.106.3.10. Client Applications

- Add initdb options `--auth-local` and `--auth-host` (Peter Eisentraut)

This allows separate control of `local` and `host` `pg_hba.conf` authentication settings. `--auth` still controls both.

- Add `--replication/--no-replication` flags to `createuser` to control replication permission (Fujii Masao)

- Add the `--if-exists` option to `dropdb` and `dropuser` (Josh Kuper Schmidt)

- Give command-line tools the ability to specify the name of the database to connect to, and fall back to `template1` if a `postgres` database connection fails (Robert Haas)

#### E.106.3.10.1. psql

- Add a display mode to auto-expand output based on the display width (Peter Eisentraut)

This adds the `auto` option to the `\x` command, which switches to the expanded mode when the normal output would be wider than the screen.

- Allow inclusion of a script file that is named relative to the directory of the file from which it was invoked (Gurjeet Singh)

This is done with a new command `\ir`.

- Add support for non-ASCII characters in `psql` variable names (Tom Lane)

- Add support for major-version-specific `.psqlrc` files (Bruce Momjian)

`psql` already supported minor-version-specific `.psqlrc` files.

- Provide environment variable overrides for `psql` history and startup file locations (Andrew Dunstan)

`PSQL_HISTORY` and `PSQLRC` now determine these file names if set.

- Add a `\setenv` command to modify the environment variables passed to child processes (Andrew Dunstan)

- Name `psql`'s temporary editor files with a `.sql` extension (Peter Eisentraut)

This allows extension-sensitive editors to select the right mode.

- Allow `psql` to use zero-byte field and record separators (Peter Eisentraut)

Various shell tools use zero-byte (NUL) separators, e.g. `find`.

- Make the `\timing` option report times for failed queries (Magnus Hagander)

Previously times were reported only for successful queries.

- Unify and tighten psql's treatment of `\copy` and `SQL COPY` (Noah Misch)

This fix makes failure behavior more predictable and honors `\set ON_ERROR_ROLLBACK`.

#### **E.106.3.10.2. Informational Commands**

- Make `\d` on a sequence show the table/column name owning it (Magnus Hagander)
- Show statistics target for columns in `\d+` (Magnus Hagander)
- Show role password expiration dates in `\du` (Fabrízio de Royes Mello)
- Display comments for casts, conversions, domains, and languages (Josh Kopershmidt)

These are included in the output of `\dC+`, `\dc+`, `\dD+`, and `\dL` respectively.

- Display comments for SQL/MED objects (Josh Kopershmidt)

These are included in the output of `\des+`, `\det+`, and `\dew+` for foreign servers, foreign tables, and foreign data wrappers respectively.

- Change `\dd` to display comments only for object types without their own backslash command (Josh Kopershmidt)

#### **E.106.3.10.3. Tab Completion**

- In psql tab completion, complete SQL keywords in either upper or lower case according to the new `COMP_KEYWORD_CASE` setting (Peter Eisentraut)
- Add tab completion support for `EXECUTE` (Andreas Karlsson)
- Allow tab completion of role references in `GRANT/REVOKE` (Peter Eisentraut)
- Allow tab completion of file names to supply quotes, when necessary (Noah Misch)
- Change tab completion support for `TABLE` to also include views (Magnus Hagander)

#### **E.106.3.10.4. pg\_dump**

- Add an `--exclude-table-data` option to `pg_dump` (Andrew Dunstan)

This allows dumping of a table's definition but not its data, on a per-table basis.

- Add a `--section` option to `pg_dump` and `pg_restore` (Andrew Dunstan)

Valid values are `pre-data`, `data`, and `post-data`. The option can be given more than once to select two or more sections.

- Make `pg_dumpall` dump all roles first, then all configuration settings on roles (Phil Sorber)

This allows a role's configuration settings to mention other roles without generating an error.

- Allow `pg_dumpall` to avoid errors if the `postgres` database is missing in the new cluster (Robert Haas)
- Dump foreign server user mappings in user name order (Peter Eisentraut)

This helps produce deterministic dump files.

- Dump operators in a predictable order (Peter Eisentraut)
- Tighten rules for when extension configuration tables are dumped by `pg_dump` (Tom Lane)
- Make `pg_dump` emit more useful dependency information (Tom Lane)

The dependency links included in archive-format dumps were formerly of very limited use, because they frequently referenced objects that appeared nowhere in the dump. Now they represent actual dependencies (possibly indirect) among the dumped objects.

- Improve `pg_dump`'s performance when dumping many database objects (Tom Lane)

### **E.106.3.11. libpq**

- Allow libpq connection strings to have the format of a URI (Alexander Shulgin)

The syntax begins with `postgres://`. This can allow applications to avoid implementing their own parser for URIs representing database connections.

- Add a connection option to disable SSL compression (Laurenz Albe)

This can be used to remove the overhead of SSL compression on fast networks.

- Add a single-row processing mode for better handling of large result sets (Kyotaro Horiguchi, Marko Kreen)

Previously, libpq always collected the entire query result in memory before passing it back to the application.

- Add `const` qualifiers to the declarations of the functions `PQconnectdbParams`, `PQconnectStartParams`, and `PQpingParams` (Lionel Elie Mamane)
- Allow the `.pgpass` file to include escaped characters in the password field (Robert Haas)
- Make library functions use `abort()` instead of `exit()` when it is necessary to terminate the process (Peter Eisentraut)

This choice does not interfere with the normal exit codes used by the program, and generates a signal that can be caught by the caller.

### **E.106.3.12. Source Code**

- Remove dead ports (Peter Eisentraut)

The following platforms are no longer supported: `dgux`, `nextstep`, `sunos4`, `svr4`, `ultrix4`, `univel`, `bsdi`.

- Add support for building with MS Visual Studio 2010 (Brar Piening)
- Enable compiling with the MinGW-w64 32-bit compiler (Lars Kanis)
- Install `plpgsql.h` into `include/server` during installation (Heikki Linnakangas)
- Improve the latch facility to include detection of postmaster death (Peter Geoghegan, Heikki Linnakangas, Tom Lane)

This eliminates one of the main reasons that background processes formerly had to wake up to poll for events.

- Use C flexible array members, where supported (Peter Eisentraut)
- Improve the concurrent transaction regression tests (`isolationtester`) (Noah Misch)
- Modify `thread_test` to create its test files in the current directory, rather than `/tmp` (Bruce Momjian)
- Improve flex and bison warning and error reporting (Tom Lane)
- Add memory barrier support (Robert Haas)

This is currently unused.

- Modify `pgindent` to use a typedef file (Bruce Momjian)
- Add a hook for processing messages due to be sent to the server log (Martin Pihlak)
- Add object access hooks for `DROP` commands (KaiGai Kohei)
- Centralize `DROP` handling for some object types (KaiGai Kohei)
- Add a `pg_upgrade` test suite (Peter Eisentraut)

- Sync regular expression code with TCL 8.5.11 and improve internal processing (Tom Lane)
- Move CRC tables to libpgport, and provide them in a separate include file (Daniel Farina)
- Add options to `git_changelog` for use in major release note creation (Bruce Momjian)
- Support Linux's `/proc/self/oom_score_adj` API (Tom Lane)

### E.106.3.13. Additional Modules

- Improve efficiency of `dblink` by using `libpq`'s new single-row processing mode (Kyotaro Horiguchi, Marko Kreen)

This improvement does not apply to `dblink_send_query()/dblink_get_result()`.

- Support `force_not_null` option in `file_fdw` (Shigeru Hanada)
- Implement dry-run mode for `pg_archivecleanup` (Gabriele Bartolini)

This only outputs the names of files to be deleted.

- Add new `pgbench` switches `--unlogged-tables`, `--tablespace`, and `--index-tablespace` (Robert Haas)
- Change `pg_test_fsync` to test for a fixed amount of time, rather than a fixed number of cycles (Bruce Momjian)

The `-o/cycles` option was removed, and `-s/seconds` added.

- Add a `pg_test_timing` utility to measure clock monotonicity and timing overhead (Ants Aasma, Greg Smith)
- Add a `tcn` (triggered change notification) module to generate `NOTIFY` events on table changes (Kevin Grittner)

#### E.106.3.13.1. `pg_upgrade`

- Adjust `pg_upgrade` environment variables (Bruce Momjian)

Rename `data`, `bin`, and `port` environment variables to begin with `PG`, and support `PGPORTOLD/PGPORTNEW`, to replace `PGPORT`.

- Overhaul `pg_upgrade` logging and failure reporting (Bruce Momjian)

Create four append-only log files, and delete them on success. Add `-r/--retain` option to unconditionally retain these files. Also remove `pg_upgrade` options `-g/-G/-l` options as unnecessary, and tighten log file permissions.

- Make `pg_upgrade` create a script to incrementally generate more accurate optimizer statistics (Bruce Momjian)

This reduces the time needed to generate minimal cluster statistics after an upgrade.

- Allow `pg_upgrade` to upgrade an old cluster that does not have a `postgres` database (Bruce Momjian)
- Allow `pg_upgrade` to handle cases where some old or new databases are missing, as long as they are empty (Bruce Momjian)
- Allow `pg_upgrade` to handle configuration-only directory installations (Bruce Momjian)
- In `pg_upgrade`, add `-o/-O` options to pass parameters to the servers (Bruce Momjian)

This is useful for configuration-only directory installs.

- Change `pg_upgrade` to use port 50432 by default (Bruce Momjian)

This helps avoid unintended client connections during the upgrade.

- Reduce cluster locking in `pg_upgrade` (Bruce Momjian)

Specifically, only lock the old cluster if link mode is used, and do it right after the schema is restored.

#### **E.106.3.13.2. `pg_stat_statements`**

- Allow `pg_stat_statements` to aggregate similar queries via SQL text normalization (Peter Geoghegan, Tom Lane)

Users with applications that use non-parameterized SQL will now be able to monitor query performance without detailed log analysis.

- Add dirtied and written block counts and read/write times to `pg_stat_statements` (Robert Haas, Ants Aasma)
- Prevent `pg_stat_statements` from double-counting `PREPARE` and `EXECUTE` commands (Tom Lane)

#### **E.106.3.13.3. `sepgsql`**

- Support `SECURITY LABEL` on global objects (KaiGai Kohei, Robert Haas)

Specifically, add security labels to databases, tablespaces, and roles.

- Allow `sepgsql` to honor database labels (KaiGai Kohei)
- Perform `sepgsql` permission checks during the creation of various objects (KaiGai Kohei)
- Add `sepgsql_setcon()` and related functions to control the `sepgsql` security domain (KaiGai Kohei)
- Add a user space access cache to `sepgsql` to improve performance (KaiGai Kohei)

#### **E.106.3.14. Documentation**

- Add a rule to optionally build HTML documentation using the stylesheet from the website (Magnus Hagander)

Use `gmake STYLE=website draft`.

- Improve `EXPLAIN` documentation (Tom Lane)
- Document that user/database names are preserved with double-quoting by command-line tools like `vacuumdb` (Bruce Momjian)
- Document the actual string returned by the client for MD5 authentication (Cyan Ogilvie)
- Deprecate use of `GLOBAL` and `LOCAL` in `CREATE TEMP TABLE` (Noah Misch)

PostgreSQL has long treated these keyword as no-ops, and continues to do so; but in future they might mean what the SQL standard says they mean, so applications should avoid using them.

## **E.107. Release 9.1.24**

**Release date:** 2016-10-27

This release contains a variety of fixes from 9.1.23. For information about new features in the 9.1 major release, see Section E.131.

This is expected to be the last PostgreSQL release in the 9.1.X series. Users are encouraged to update to a newer release branch soon.

### **E.107.1. Migration to Version 9.1.24**

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.115.

## E.107.2. Changes

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gieth)

The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix timeout length when `VACUUM` is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing `VACUUM` to give up on truncation much more easily than intended. Set it to the intended value.

- Remove artificial restrictions on the values accepted by `numeric_in()` and `numeric_recv()` (Tom Lane)

We allow numeric values up to the limit of the storage format (more than  $1e1000000$ ), so it seems fairly pointless that `numeric_in()` rejected scientific-notation exponents above 1000. Likewise, it was silly for `numeric_recv()` to reject more than 1000 digits in an input value.

- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
- Disallow starting a standalone backend with `standby_mode` turned on (Michael Paquier)

This can't do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn't designed with this situation in mind.

- Don't try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

- Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

- Make `ecpg's --help` and `--version` options work consistently with our other executables (Haribabu Kommi)
- Fix `contrib/intarray/bench/bench.pl` to print the results of the `EXPLAIN` it does when given the `-e` option (Daniel Gustafsson)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)

If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the `pg_timezone_abbrevs` view to fail altogether.

- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are

in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the `pg_timezone_names` view nor used for output.

In this update, `AMT` is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the `Default` abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

## E.108. Release 9.1.23

**Release date:** 2016-08-11

This release contains a variety of fixes from 9.1.22. For information about new features in the 9.1 major release, see Section E.131.

The PostgreSQL community will stop releasing updates for the 9.1.X release series in September 2016. Users are encouraged to update to a newer release branch soon.

### E.108.1. Migration to Version 9.1.23

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.115.

### E.108.2. Changes

- Fix possible mis-evaluation of nested `CASE-WHEN` expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A `CASE` expression appearing within the test value subexpression of another `CASE` could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a `CASE` expression could result in passing the wrong test value to functions called within a `CASE` expression in the SQL function's body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

- Fix client programs' handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in `vacuumdb` and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a `conninfo` string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in `psql`'s `\connect` and `\password` commands to match the documentation.

Introduce a new `-reuse-previous` option in `psql`'s `\connect` command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a `conninfo` string, as before.) This allows secure handling of database names containing special characters in `pg_dumpall` scripts.

`pg_dumpall` now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes `pg_dumpall` or other routine maintenance operations. (CVE-2016-5424)

- Fix corner-case misbehaviors for `IS NULL/IS NOT NULL` applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that `IS NULL` should return `TRUE` for a row of all null values (thus `ROW(NULL, NULL) IS NULL` yields `TRUE`), but this is not meant to apply recursively (thus `ROW(NULL, ROW(NULL, NULL)) IS NULL` yields `FALSE`). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing `TRUE` in both cases), and `contrib/postgres_fdw` could produce remote queries that misbehaved similarly.

- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)
- Prevent crash in `close_ps()` (the `point ## lseg` operator) for NaN input coordinates (Tom Lane)

Make it return `NULL` instead of crashing.

- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)

In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.

- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)

Previously, these cases locked the target tuple (by setting its `XMAX`) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.

- Avoid consuming a transaction ID during `VACUUM` (Alexander Korotkov)

Some cases in `VACUUM` unnecessarily caused an `XID` to be assigned to the current transaction. Normally this is negligible, but if one is up against the `XID` wraparound limit, consuming more `XIDs` during anti-wraparound vacuums is a very bad thing.

- Avoid canceling hot-standby queries during `VACUUM FREEZE` (Simon Riggs, Álvaro Herrera)

`VACUUM FREEZE` on an otherwise-idle master server could result in unnecessary cancellations of queries on its standby servers.

- When a manual `ANALYZE` specifies a column list, don't reset the table's `changes_since_analyze` counter (Tom Lane)

If we're only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.

- Fix `ANALYZE`'s overestimation of `n_distinct` for a unique or nearly-unique column with many null entries (Tom Lane)

The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.

- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)

Normally this isn't much of a problem because the vacuum doesn't take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.

- Fix `contrib/btree_gin` to handle the smallest possible `bigint` value correctly (Peter Eisentraut)
- Teach `libpq` to correctly decode server version from future servers (Peter Eisentraut)

It's planned to switch to two-part instead of three-part server version numbers for releases after 9.6. Make sure that `PQserverVersion()` returns the correct value for such cases.

- Fix `ecpg`'s code for `unsigned long long` array elements (Michael Meskes)
- Make `pg_basebackup` accept `-Z 0` as specifying no compression (Fujii Masao)

- Revert to the old heuristic timeout for `pg_ctl start -w` (Tom Lane)

The new method adopted as of release 9.1.20 does not work when `silent_mode` is enabled, so go back to the old way.

- Fix makefiles' rule for building AIX shared libraries to be safe for parallel make (Noah Misch)
- Fix TAP tests and MSVC scripts to work when build directory's path name contains spaces (Michael Paquier, Kyotaro Horiguchi)
- Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)

Change some test data that triggered the unusual sorting rules of these locales.

- Update our copy of the timezone code to match IANA's tzcode release 2016c (Tom Lane)

This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

## E.109. Release 9.1.22

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.1.21. For information about new features in the 9.1 major release, see Section E.131.

The PostgreSQL community will stop releasing updates for the 9.1.X release series in September 2016. Users are encouraged to update to a newer release branch soon.

### E.109.1. Migration to Version 9.1.22

A dump/restore is not required for those running 9.1.X.

However, if you are upgrading from a version earlier than 9.1.16, see Section E.115.

### E.109.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it's clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It's possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any *N*-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)
- Fix possible misbehavior of `TH`, `th`, and `Y, YYY` format codes in `to_timestamp()` (Tom Lane)

These could advance off the end of the input string, causing subsequent format codes to read garbage.

- Fix dumping of rules and views in which the `array` argument of a `value operator ANY (array)` construct is a sub-SELECT (Tom Lane)
- Make `pg_regress` use a startup timeout from the `PGCTLTIMEOUT` environment variable, if that's set (Tom Lane)

This is for consistency with a behavior recently added to `pg_ctl`; it eases automated testing on slow machines.

- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)

In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.

- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Avoid possibly-unsafe use of Windows' `FormatMessage()` function (Christian Ullrich)
